

# IBM Quantum devices for research in quantum information

Matteo Rossi  
University of Turku (FI)

Milano  
16 march 2021

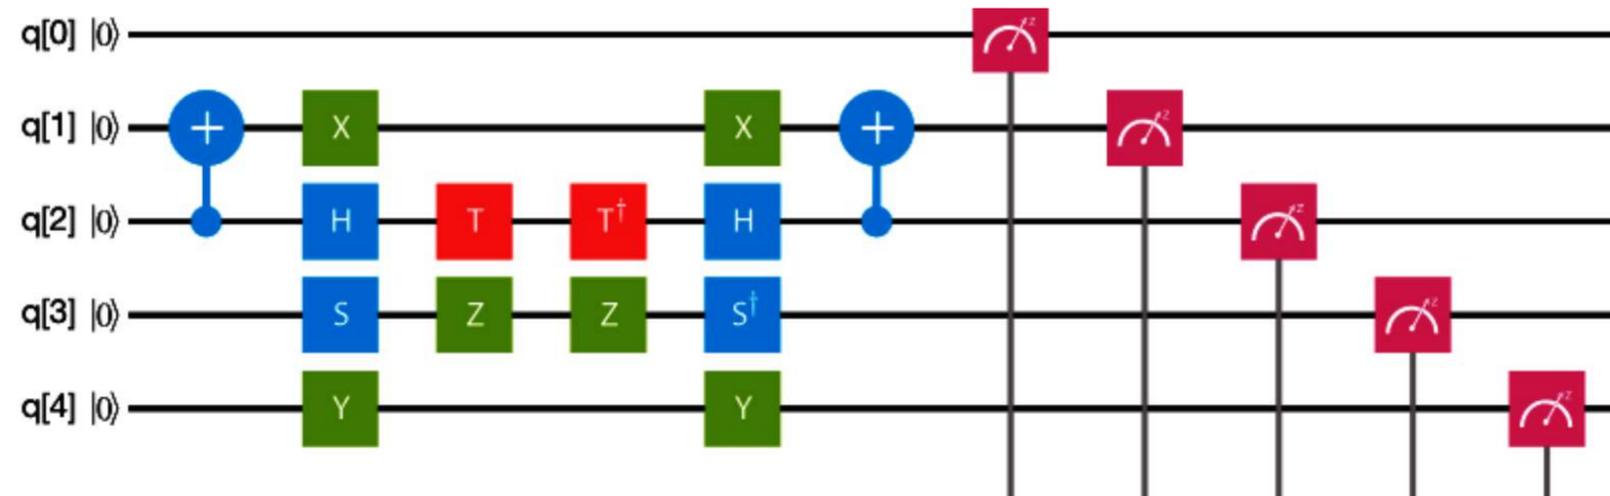

# Overview

- Intro: Gate-based quantum computers and IBM Q
- Tutorial: Typical usage of IBM Q
- Applications:
  - Simulating open quantum systems (collisional models)
  - POVMS (in near-term algorithms)

# Introduction

# Gate-based quantum computers

A set of **basis gates** allows for **universal quantum computation**.

$$\text{X} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

$$\sqrt{\text{X}} = \frac{1}{2} \begin{pmatrix} 1+i & 1-i \\ 1-i & 1+i \end{pmatrix}$$

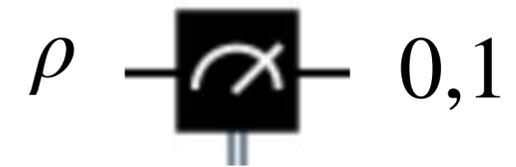

$$\text{R}_Z = \begin{pmatrix} e^{-i\frac{\lambda}{2}} & 0 \\ 0 & e^{i\frac{\lambda}{2}} \end{pmatrix}$$

CNOT

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}$$

Projective measurement

# Gate-based quantum computers

## Trapped ions

## Photonic

## Cloud providers

# IBM Q Experience

## Now IBM Quantum

- Launched in 2016 (a 5-qubit device controlled from the browser)
- Now counts 25 quantum devices from 1 to 65 qubits
- Devices are accessible from the cloud, using the browser or the Qiskit SDK
- Free registration gives immediate access to 8 devices and simulators
- Universities can join the IBM Q Network and get priority access.
- With research proposals (and lots of bureaucracy) access to restricted devices

# Quantum services

View the status and details of IBM Quantum's systems and simulators, and track which are available to you.

ibmq\_bogota

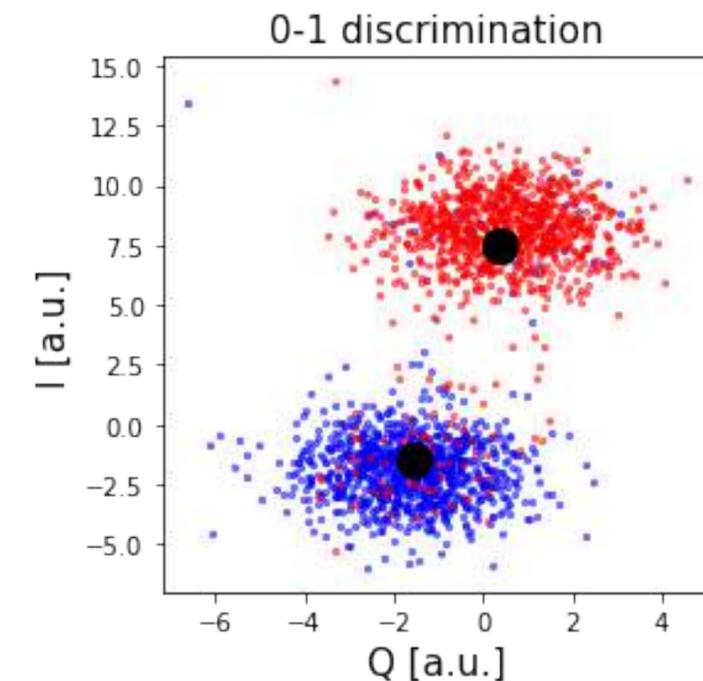

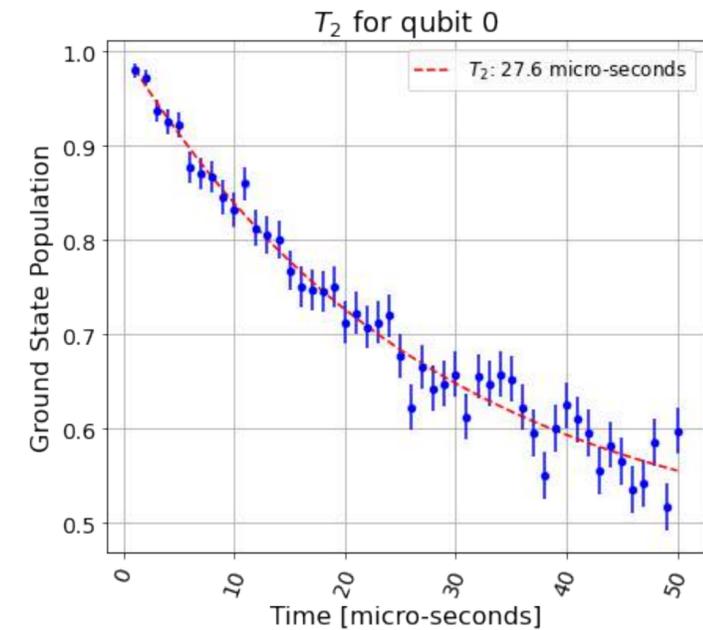

**d**

# Noise

Quantum gate-based devices are characterized by various sources of noise

- Finite qubit coherence times  $T_1$ ,  $T_2$  (interaction with the environment)
- Gate error rates (imperfect pulses, interaction with env., crosstalk)
- Measurement errors (discrimination errors, imperfect pulses, crosstalk)

# Noise

# Quantum volume

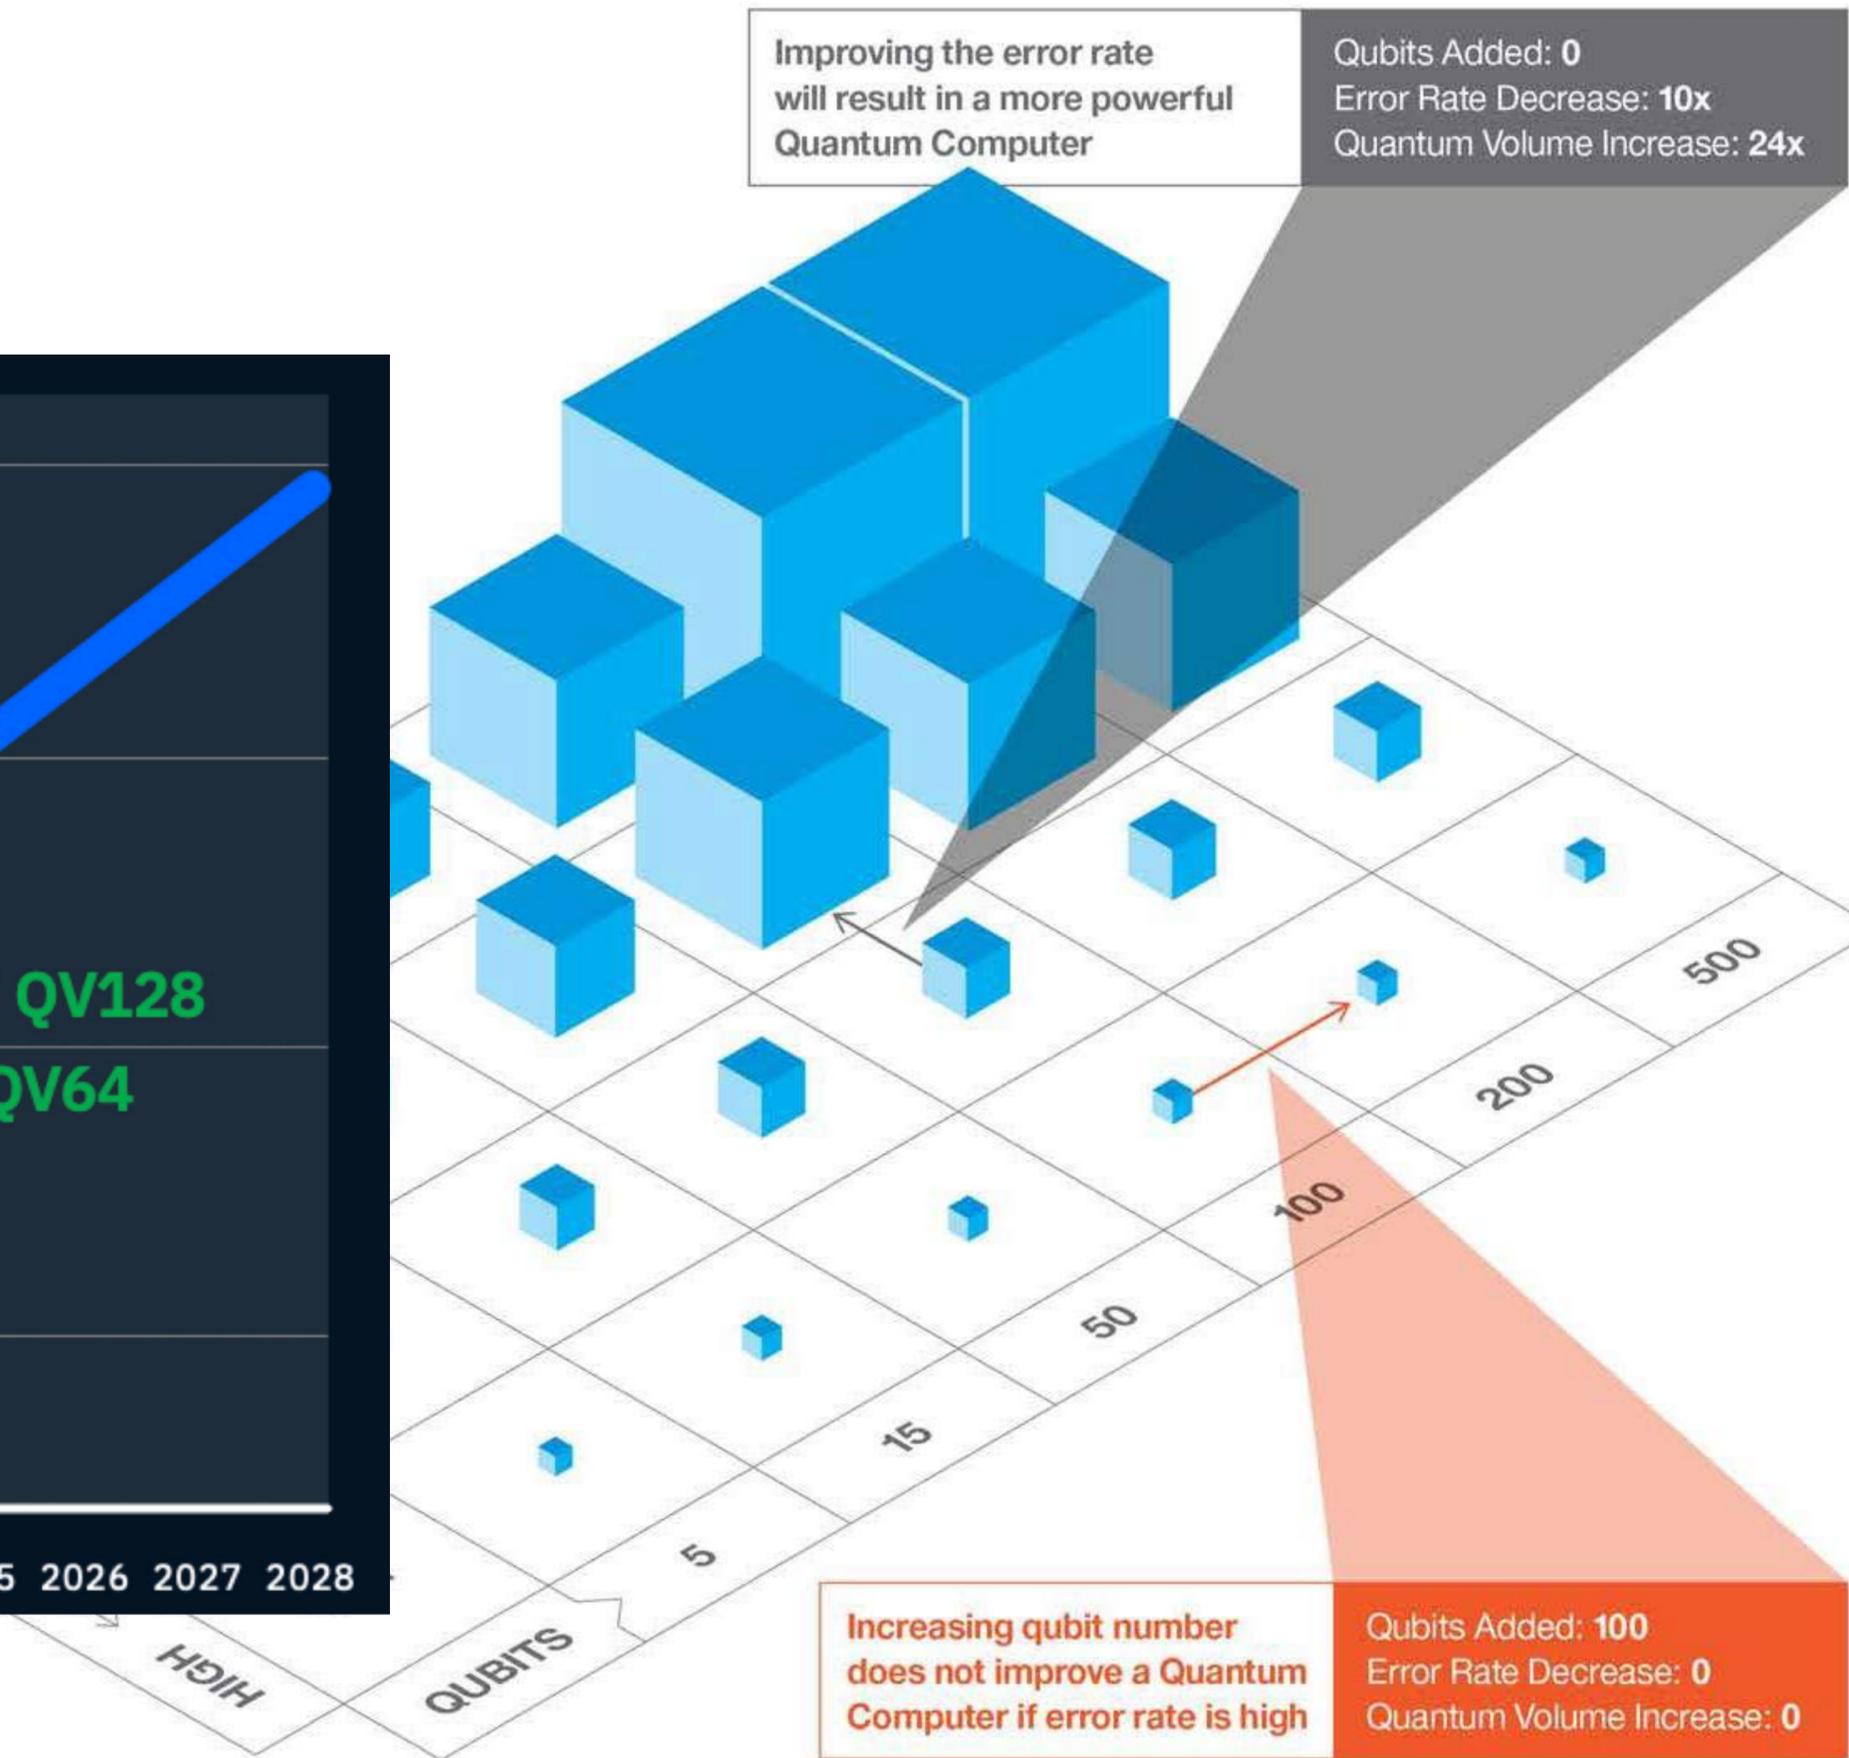

- The number of qubits is irrelevant if the depth of the circuit is limited by noise
- Limited connectivity effectively increases the depth (qubit swaps required)

# Tutorial

# How to use IBM Q devices

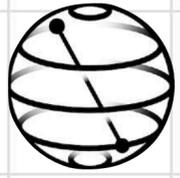

The screenshot displays the IBM Quantum Lab interface for a quantum circuit named "Bell state". The circuit consists of two qubits, q0 and q1. Qubit q0 starts with an H gate, followed by a CNOT gate with q1 as the target. Qubit q1 starts with a CNOT gate with q0 as the control, followed by an H gate. The circuit is visualized as a sequence of gates: H, CNOT, CNOT, H.

The "Probabilities" panel shows a bar chart of the computational basis states. The y-axis is "Probability (%)" from 0 to 100. The x-axis is "Computational basis states" with values 00, 01, 10, and 11. The bars for 00 and 11 are at 50% probability, while 01 and 10 are at 0%.

The "Statevector" panel shows a bar chart of the amplitude for each computational basis state. The y-axis is "Amplitude" from 0 to 0.8. The x-axis is "Computational basis states" with values 00, 01, 10, and 11. The bars for 00 and 11 are at approximately 0.707, while 01 and 10 are at 0. Below the chart is a phase wheel and an "Output state" box containing the vector  $[0.707+0j, 0+0j, 0+0j, 0.707+0j]$ .

The OpenQASM 2.0 code on the right is:

```

Learn Quantum Computation using Qiskit

What is Quantum?

0. Prerequisites

1. Quantum States and Qubits

- 1.1 Introduction
- 1.2 The Atoms of Computation
- 1.3 Representing Qubit States
- 1.4 Single Qubit Gates
- 1.5 The Case for Quantum

2. Multiple Qubits and Entanglement

- 2.1 Introduction
- 2.2 Multiple Qubits and Entangled States
- 2.3 Phase Kickback
- 2.4 More Circuit Identities
- 2.5 Proving Universality
- 2.6 Classical Computation on a Quantum Computer

3. Quantum Protocols and Quantum Algorithms

- 3.1 Defining Quantum Circuits
- 3.2 Deutsch-Jozsa Algorithm

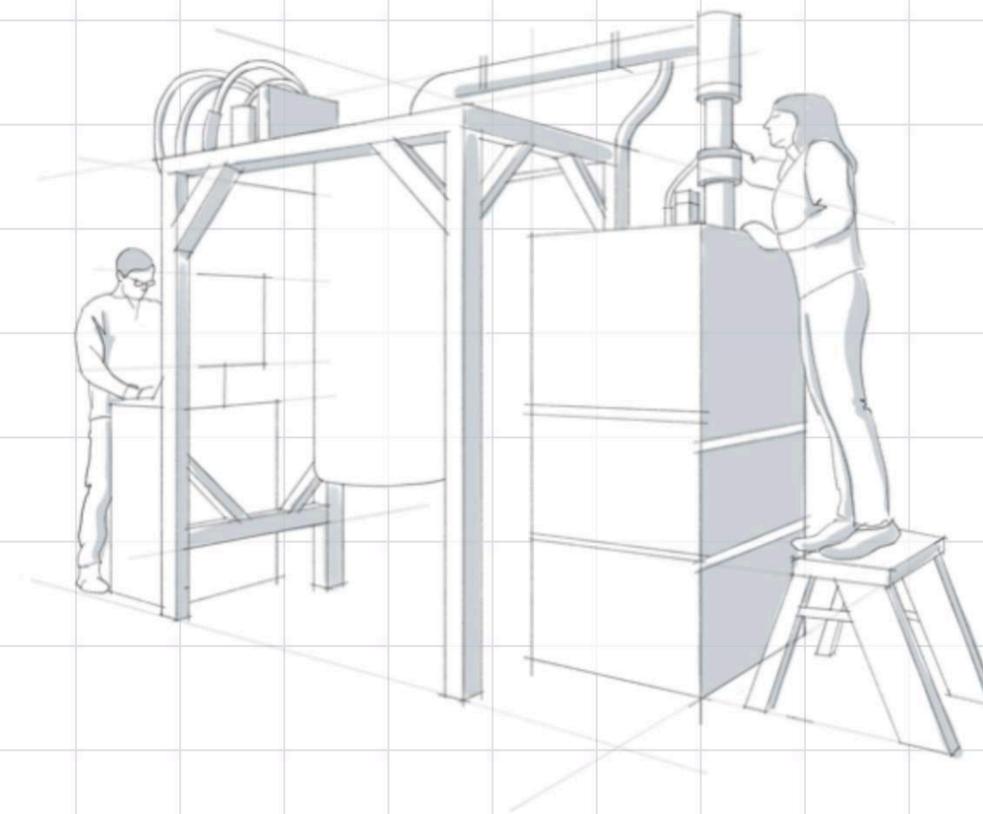

## Learn Quantum Computation using Qiskit

Greetings from the Qiskit Community team! This textbook is a university quantum algorithms/computation course supplement based on Qiskit to help learn:

1. The mathematics behind quantum algorithms
2. Details about today's non-fault-tolerant quantum devices
3. Writing code in Qiskit to implement quantum algorithms on IBM's cloud quantum systems

[Read the textbook](#) →

# Qiskit Hello world!

```
pip install qiskit
```

```
from qiskit import IBMQ, Aer, execute
from qiskit import QuantumRegister, ClassicalRegister, QuantumCircuit
```

Circuit definition:

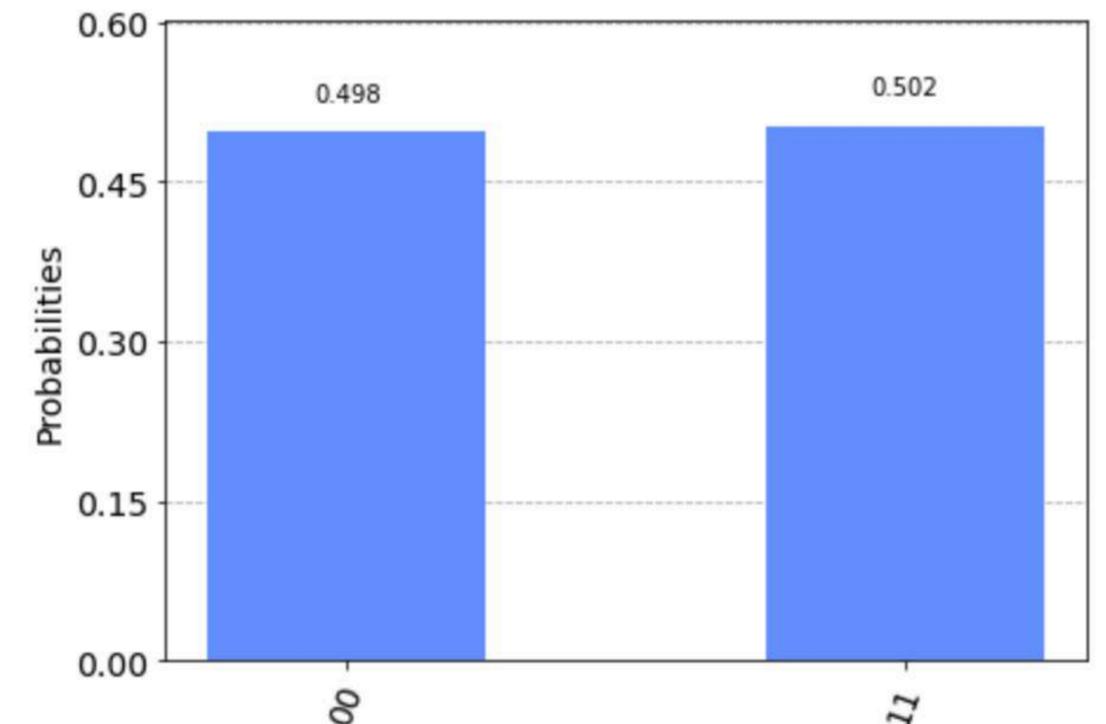

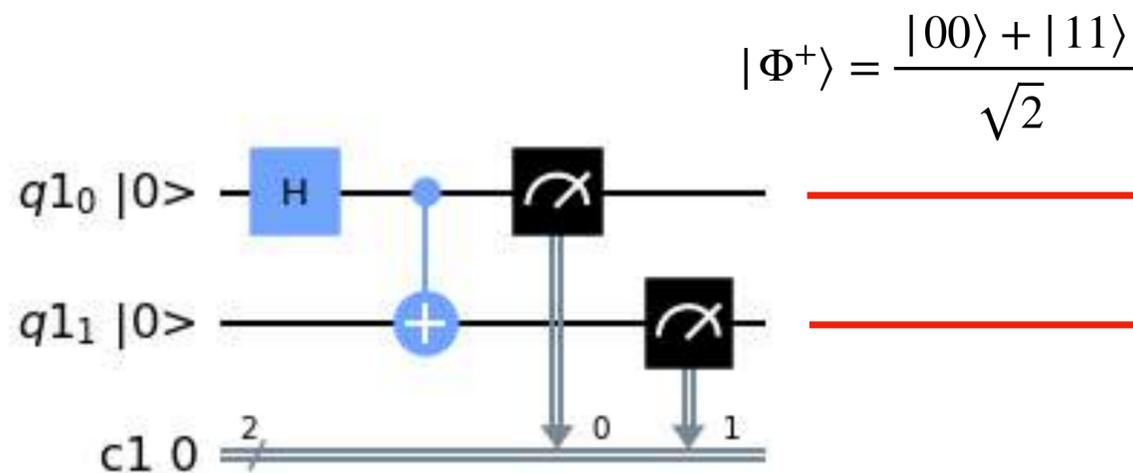

```
qr = QuantumRegister(2)
cr = ClassicalRegister(2)
qc = QuantumCircuit(qr, cr)
qc.h(0)
qc.cx(0, 1)
qc.measure(0, 0)
qc.measure(1, 1)
qc.draw(output='mpl', initial_state=True)
```

Simulation:

```
job = execute(qc, Aer.get_backend('qasm_simulator'), shots=8192)
result = job.result()
result.get_counts()
```

```
{'00': 4076, '11': 4116}
```

LSB on the right!!!!

# Qiskit Hello world!

## Execution on a real device

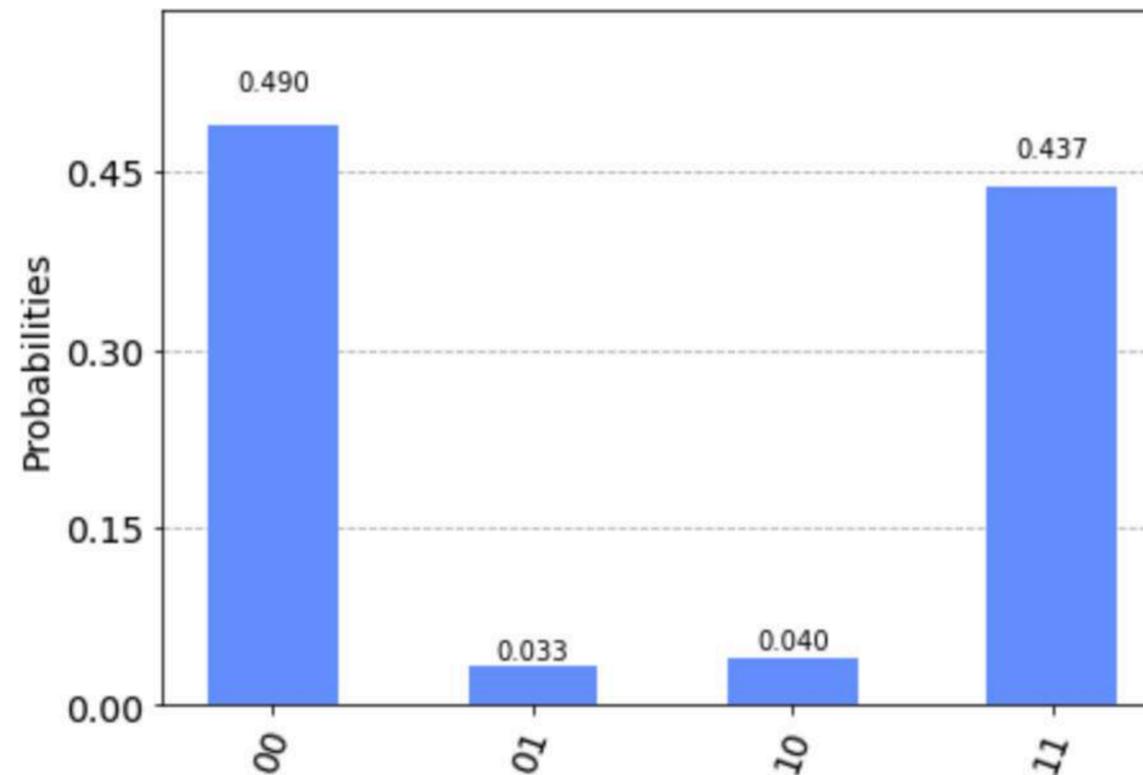

```
IBMQ.load_account()  
provider = IBMQ.get_provider(hub='ibm-q-research', group='uni-turku-4', project='main')  
backend = provider.get_backend('ibmq_bogota')
```

```
job = execute(qc, backend, shots=8192)
```

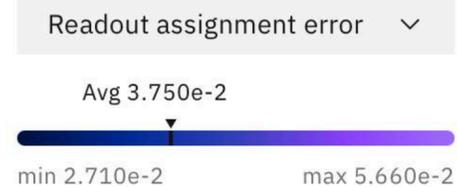

```
job.status()
```

```
<JobStatus.DONE: 'job has successfully run'>
```

```
result = job.result()  
plot_histogram(result.get_counts())
```

Qubit:

Connection:

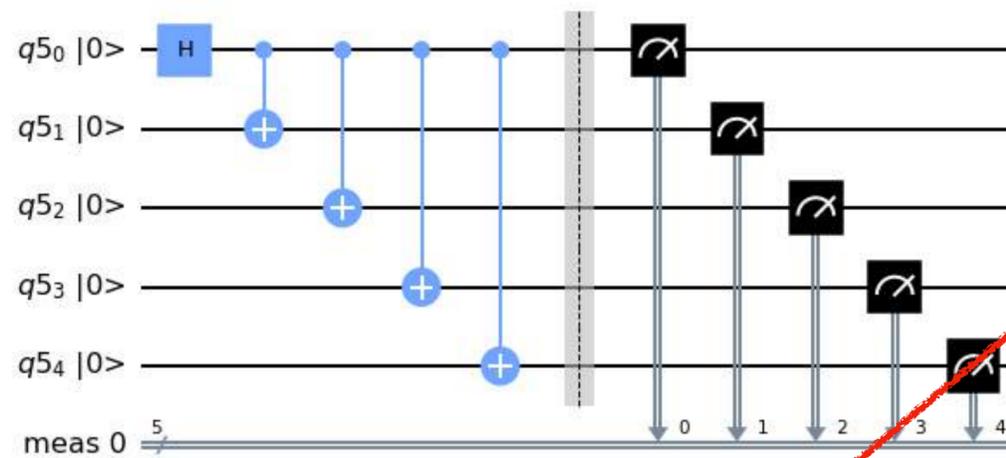

# Improving your results

```
qr = QuantumRegister(5)
qc = QuantumCircuit(qr)

qc.h(0)
for i in range(4):
    qc.cx(0, i + 1)

qc.measure_all()
```

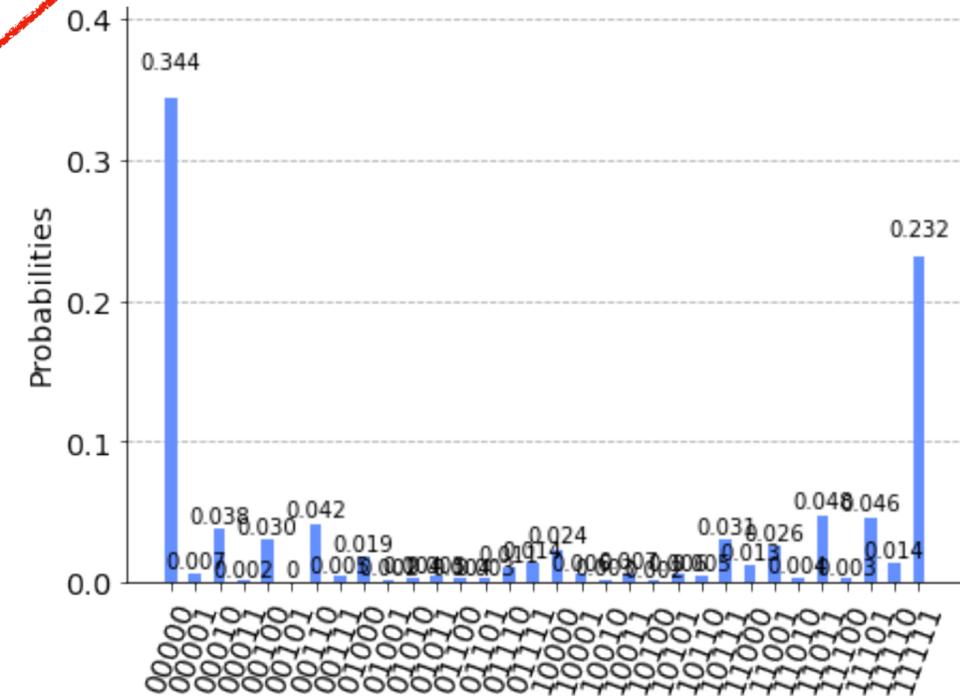

$$\frac{|00000\rangle + |11111\rangle}{\sqrt{2}}$$

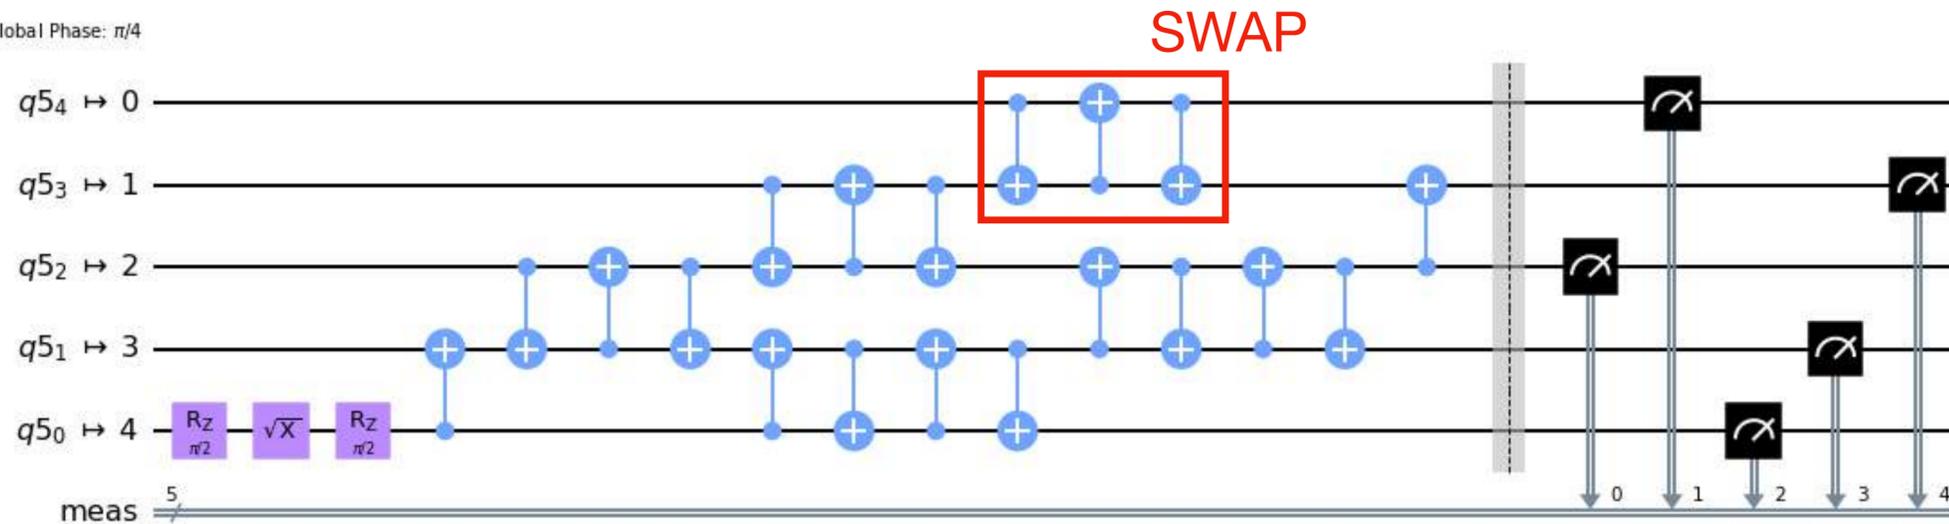

```
from qiskit import transpile
tqc = transpile(qc, backend, optimization_level=1)
```

ibmq\_bogota

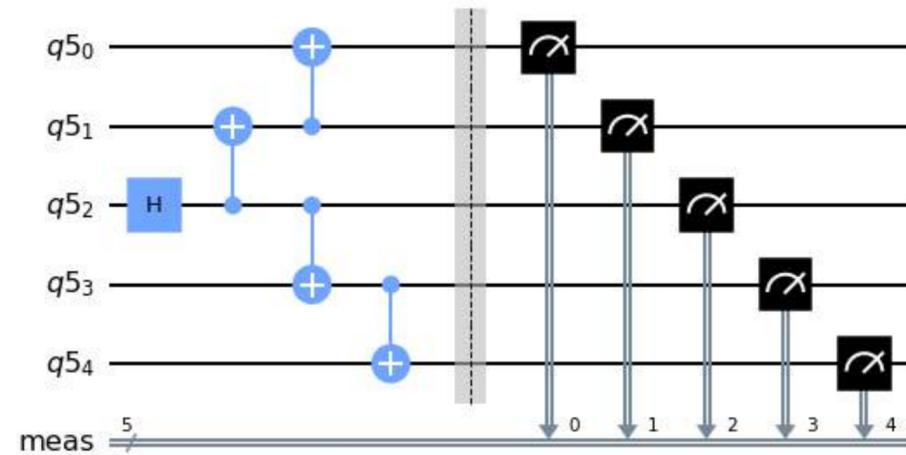

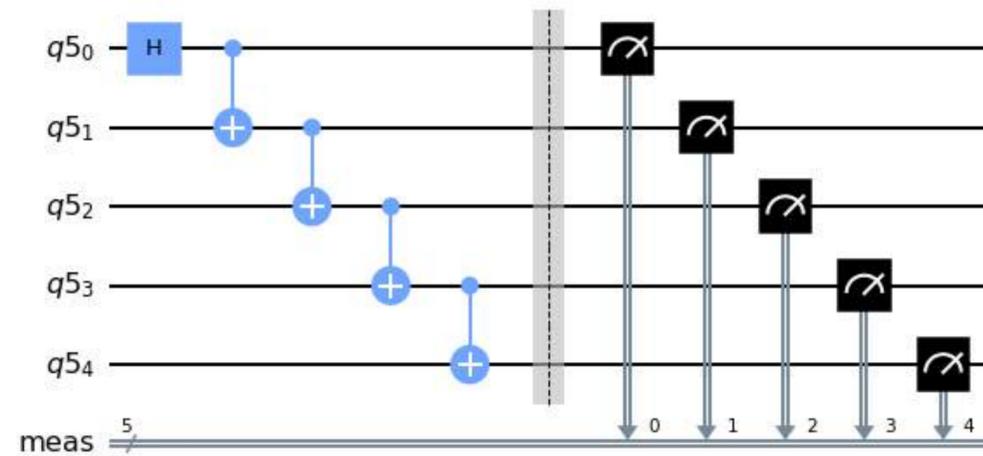

```
job = execute(qc, backend, shots=8192)
```

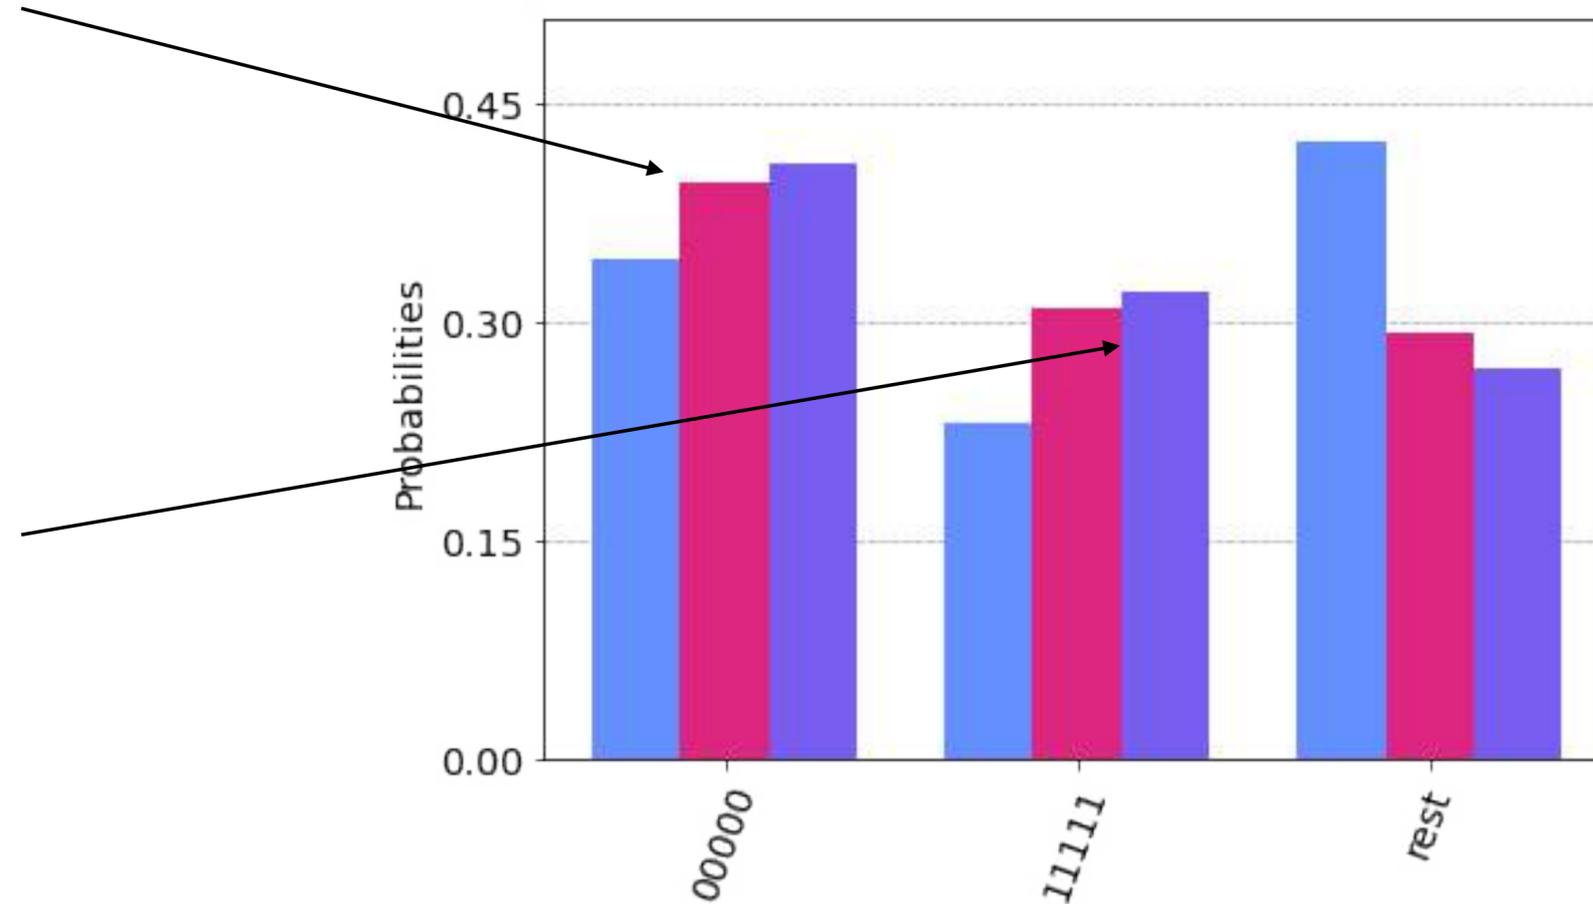

Global Phase:  $\pi/4$

# Improving your results

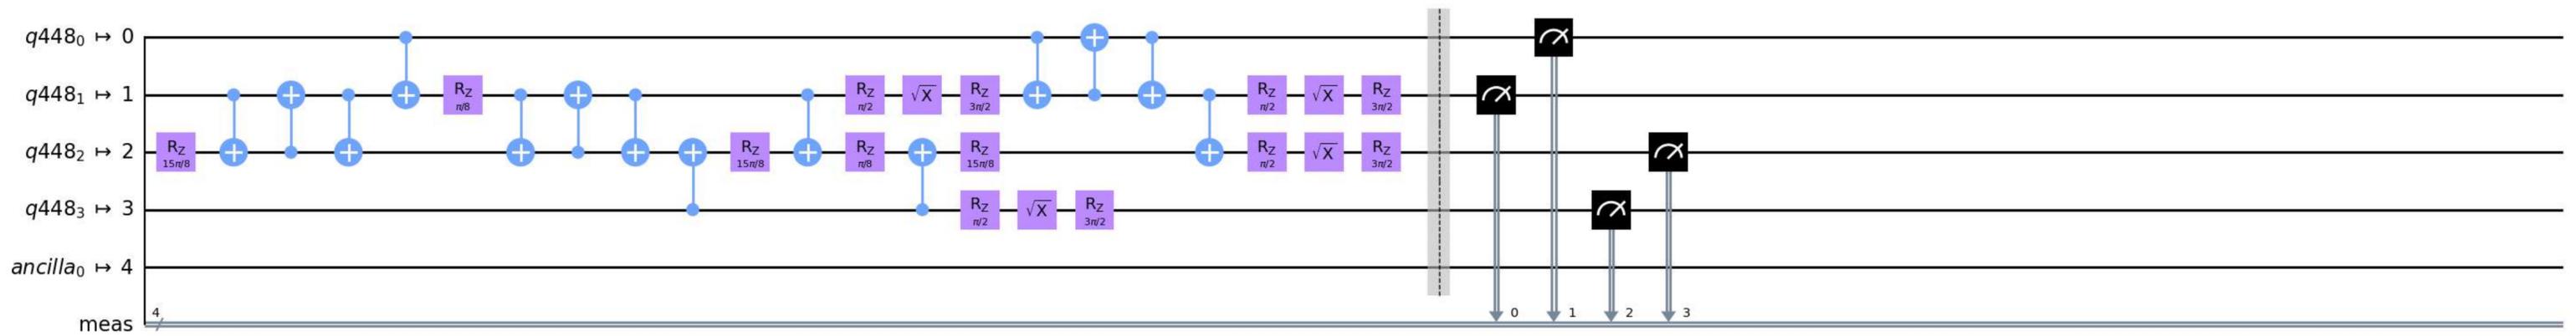

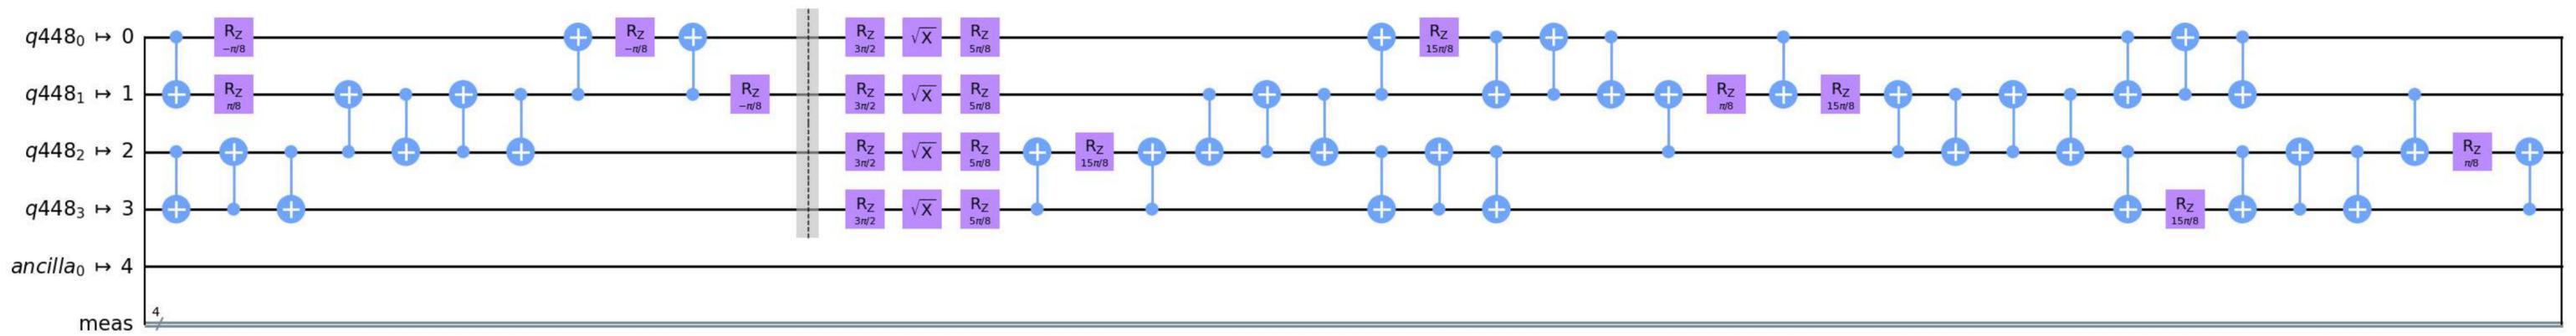

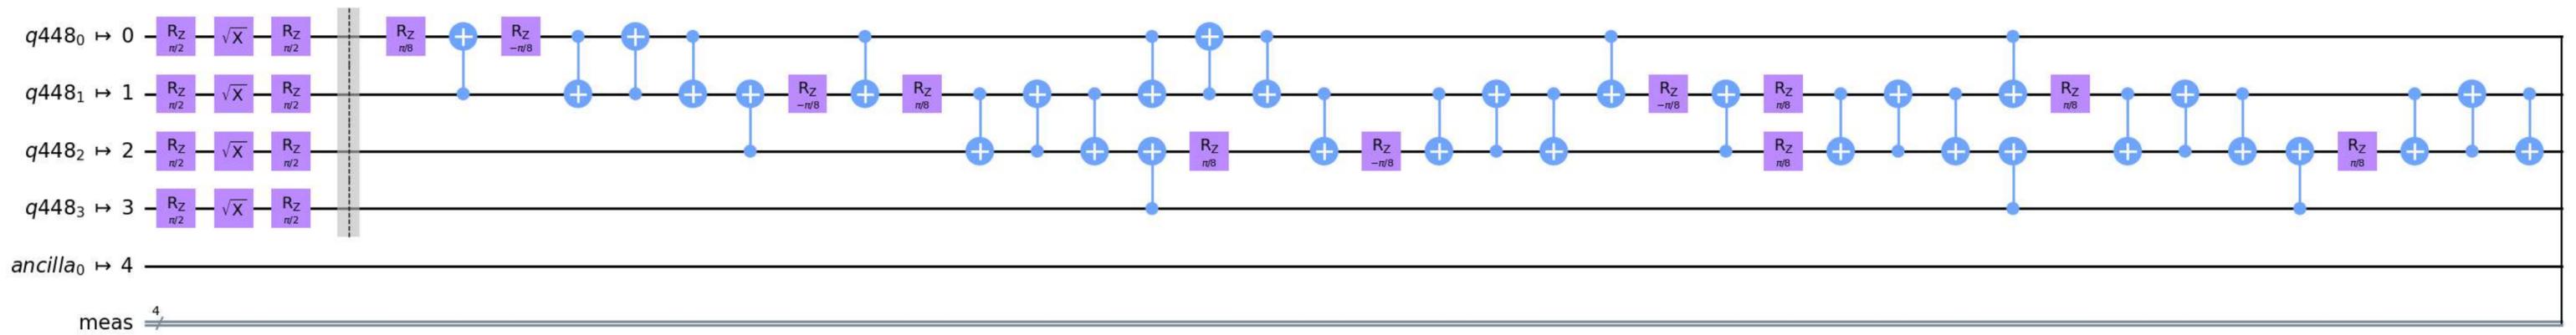

ibmq\_bogota

# Grover search

Global Phase:  $\pi/8$

# Improving your results

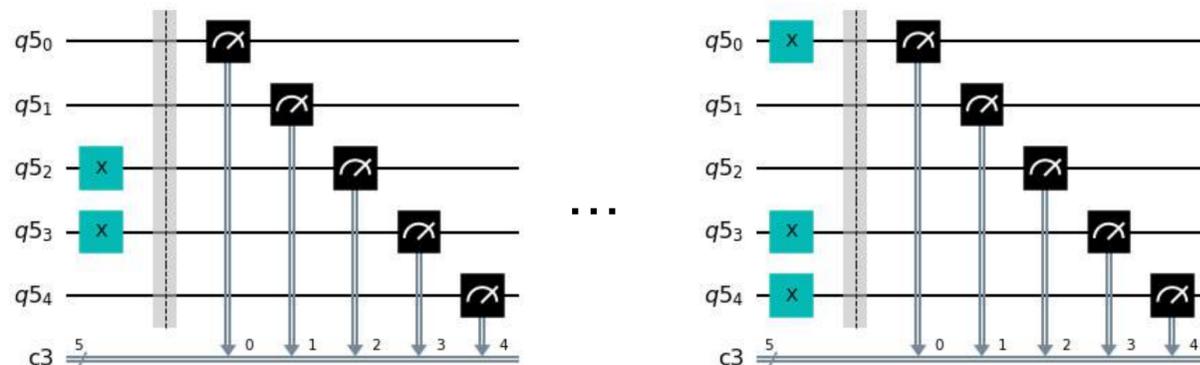

## Measurement noise mitigation

Prepares all  $2^n$  bitstrings and measures them

```
## Mitigation
# Import measurement calibration functions
from qiskit.ignis.mitigation.measurement import (complete_meas_cal,
                                                CompleteMeasFitter)

meas_calibs, state_labels = complete_meas_cal(qr=qr,
                                             qubit_list=range(5),
                                             circlabel='mcal')

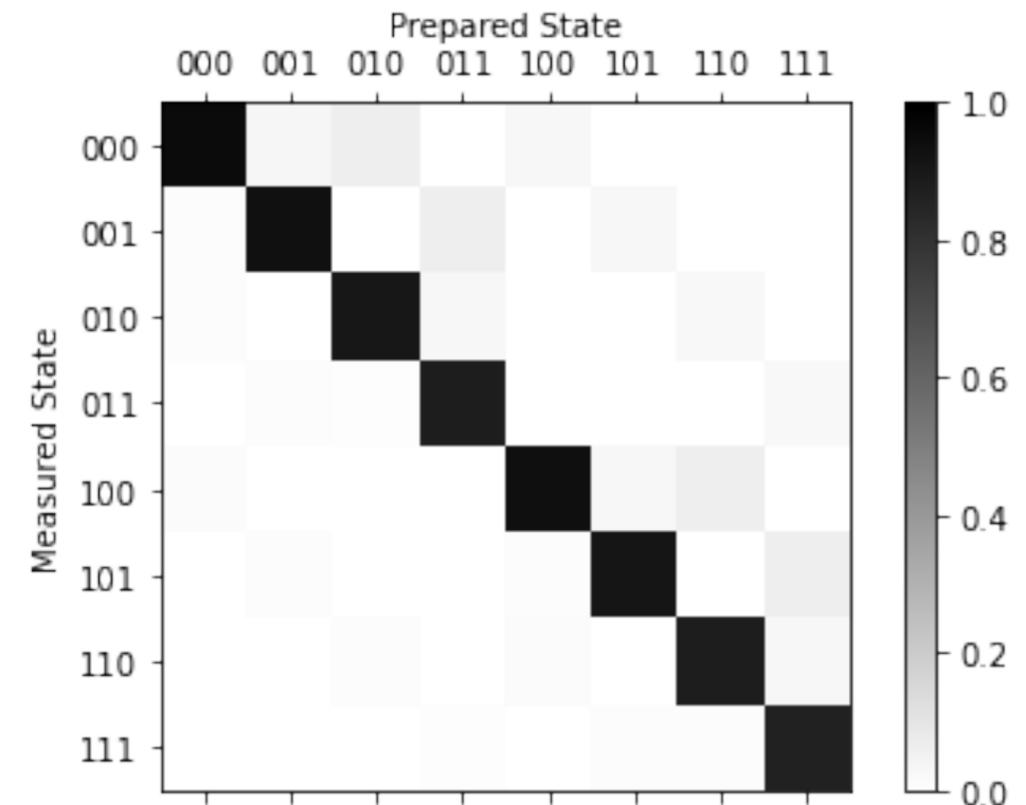

calib_job = qiskit.execute(meas_calibs, backend=backend, shots=8192)
```

Builds a confusion matrix

```
meas_fitter = CompleteMeasFitter(cal_results,
                                state_labels,
                                qubit_list=range(5),
                                circlabel='mcal')

# Plot the calibration matrix
meas_fitter.plot_calibration()
```

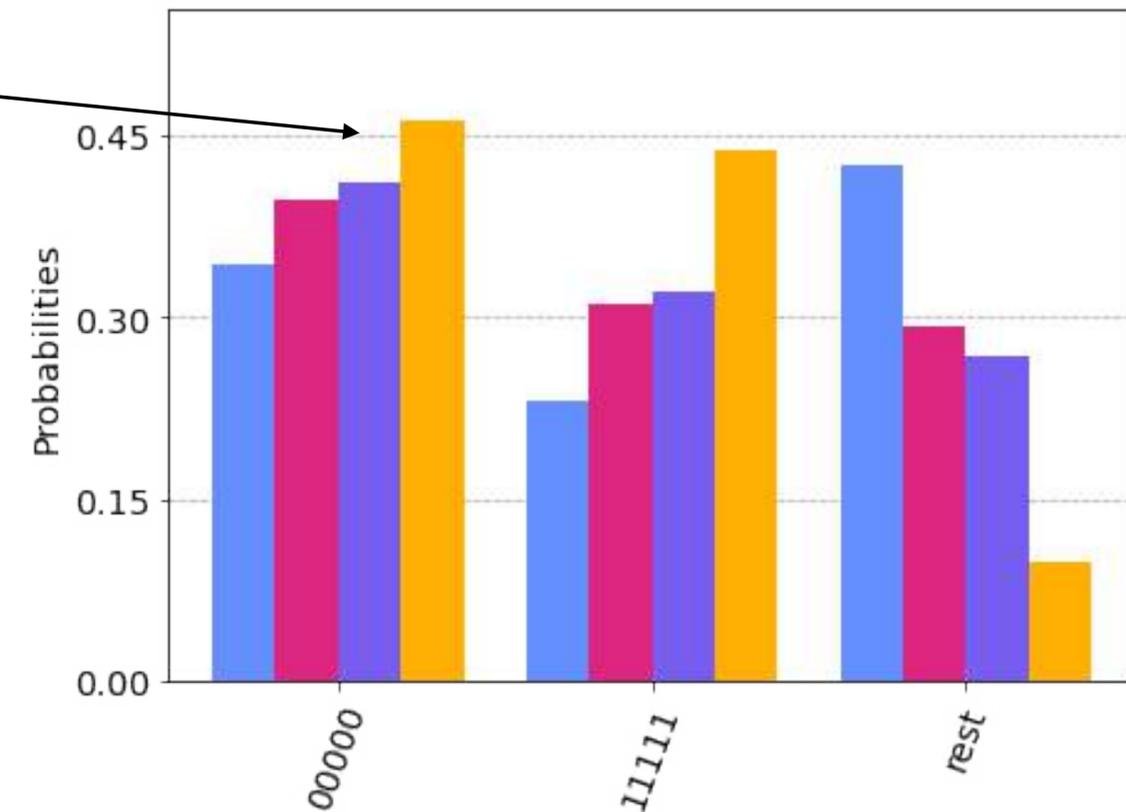

# Improving your results

## Measurement noise mitigation

Applies the inverse of the confusion matrix to the results

```
meas_filter = meas_fitter.filter  
mitigated_result = meas_filter.apply(result)
```

For short circuits the readout error is quite relevant!

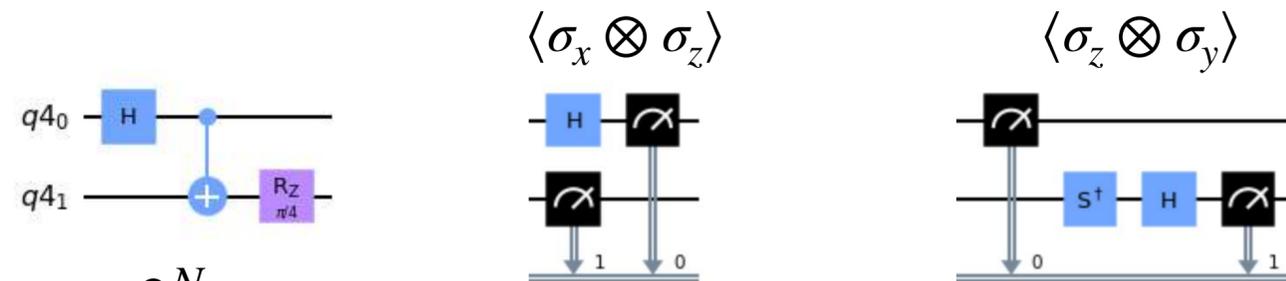

# n-qubit tomography

## Reconstruct the quantum state $\rho$

```
# Tomography
from qiskit.ignis.verification.tomography import state_tomography_circuits
from qiskit.ignis.verification.tomography import StateTomographyFitter
```

```
# Construct the tomography circuits by passing the initial circuit
# and a list of the qubits of interest
tomo_circuits = state_tomography_circuits(qc, [qr[0], qr[1]])
```

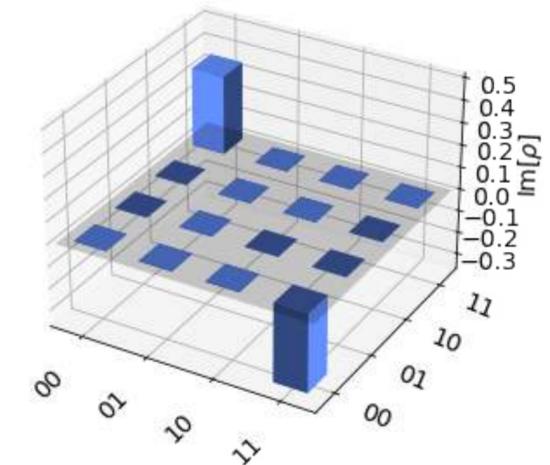

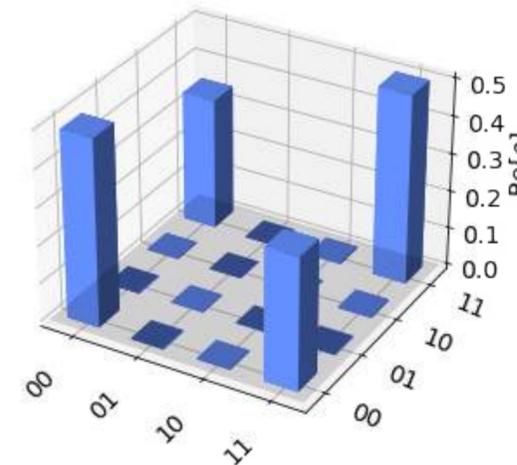

Total:  $3^N$  circuits

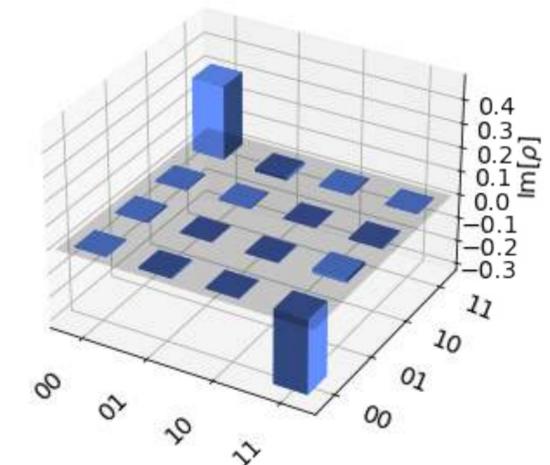

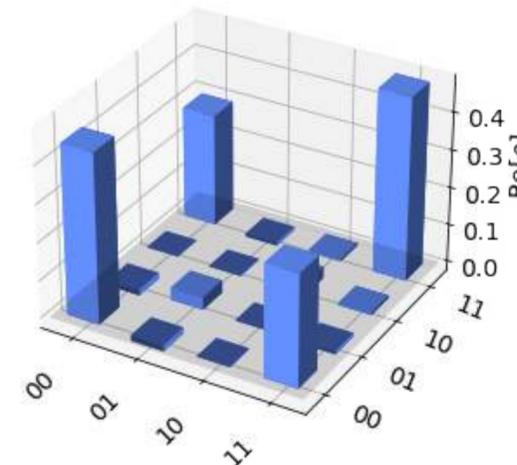

```
# The fitter takes the result of the list of tomography circuits
# and reconstructs the density matrix using maximum likelihood
tomo_fitter = StateTomographyFitter(result, tomo_circuits)
rho = tomo_fitter.fit()
```

Also process tomography!

Simulation

Experiment

Fidelity: 0.92

# Take home messages

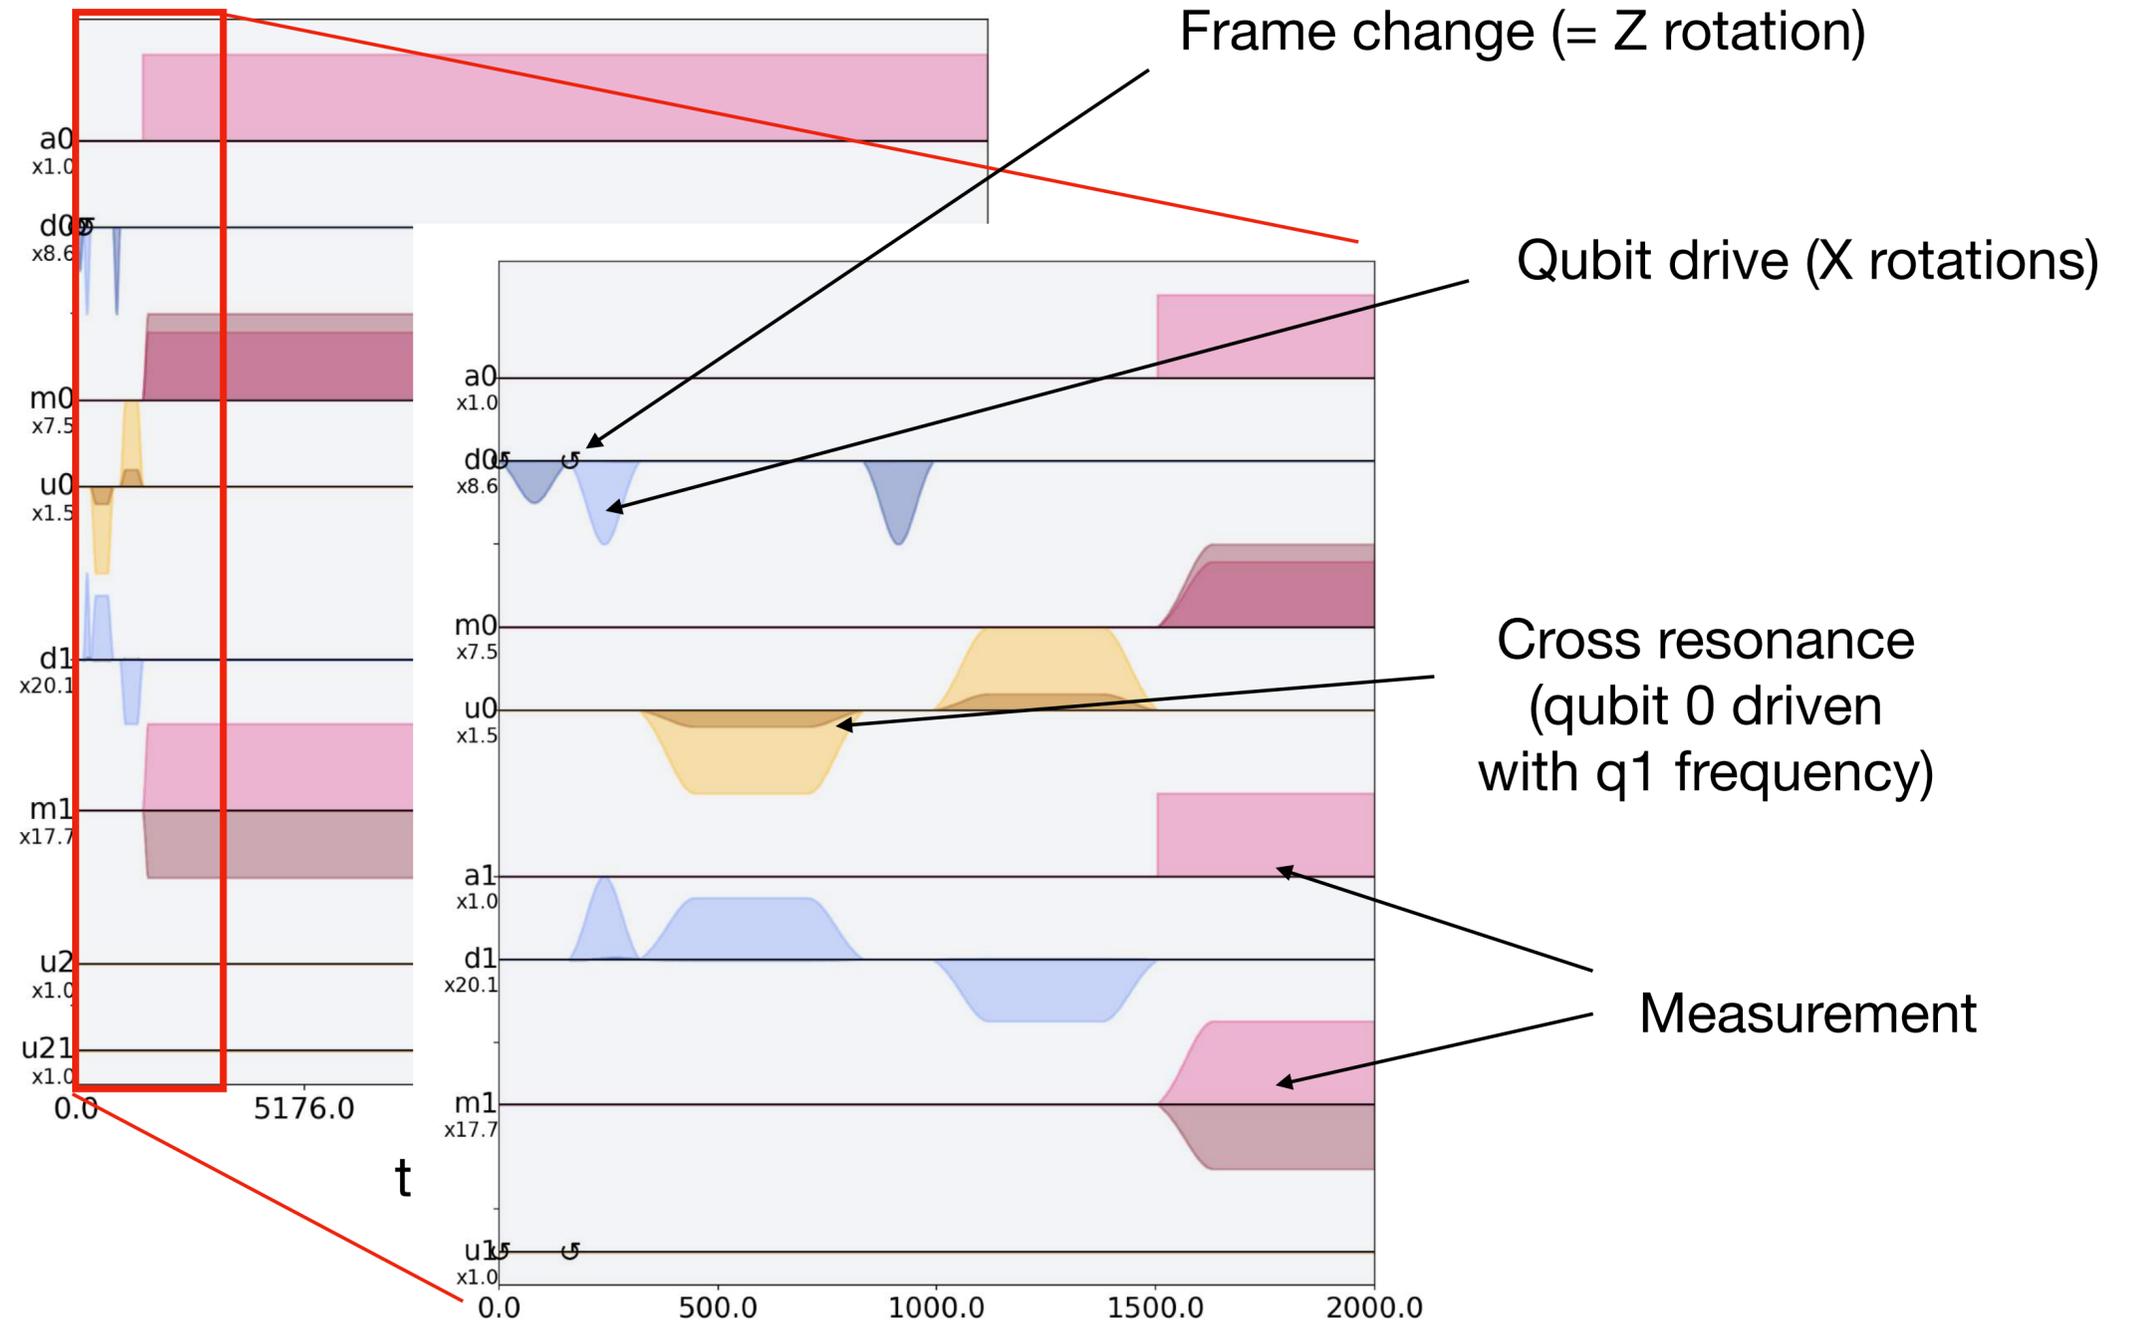

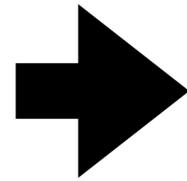

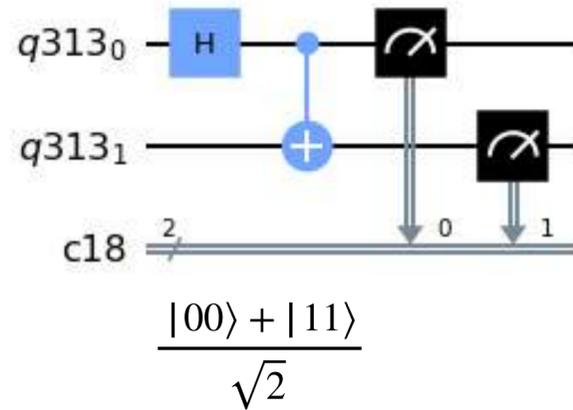

- Noise and **connectivity layout** pose limitations to the size of circuits
- **Do not trust the compilers!** They are still rudimentary
- **Handmade short circuits** that take into account the connectivity layout can give good experimental results
- `qiskit.ignis` gives tools such as **measurement noise mitigation** and state and process **tomography** to improve and analyze the results

# Pulses

```

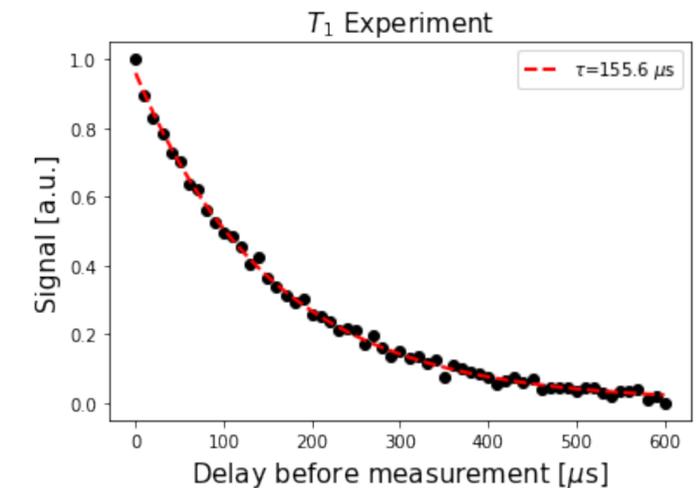

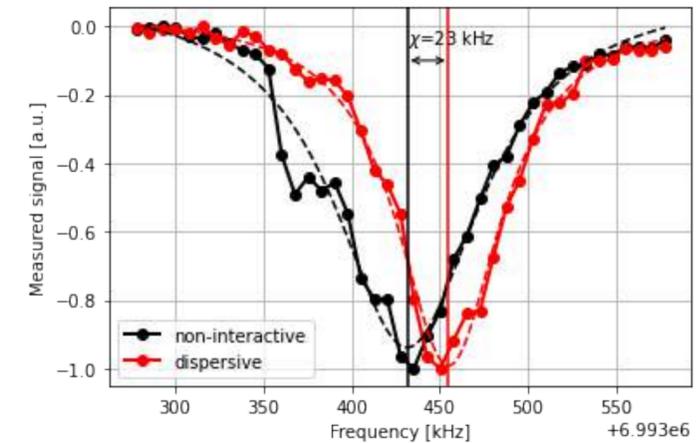

from qiskit.compiler import schedule
tqc = transpile(qc, backend)
sched = schedule(tqc, backend)

```

# Pulses

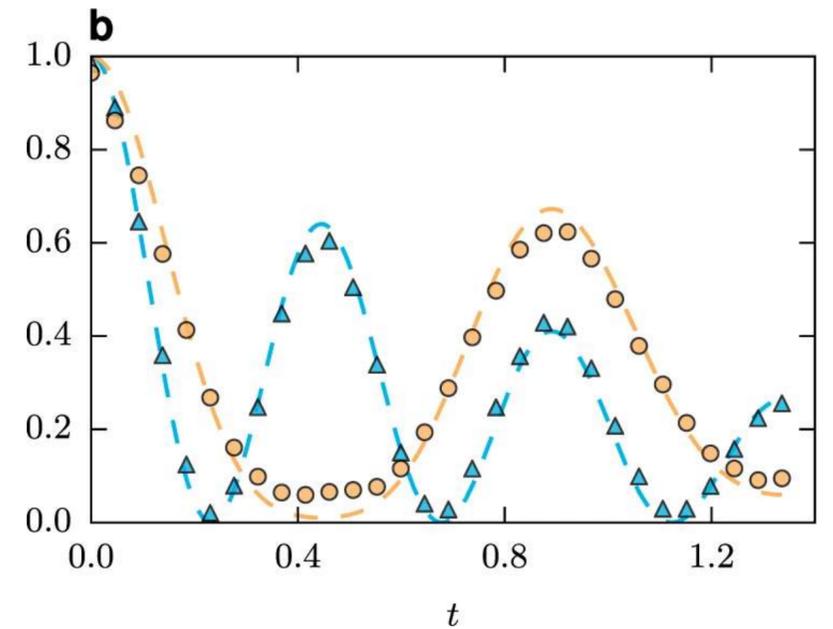

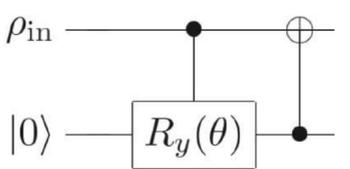

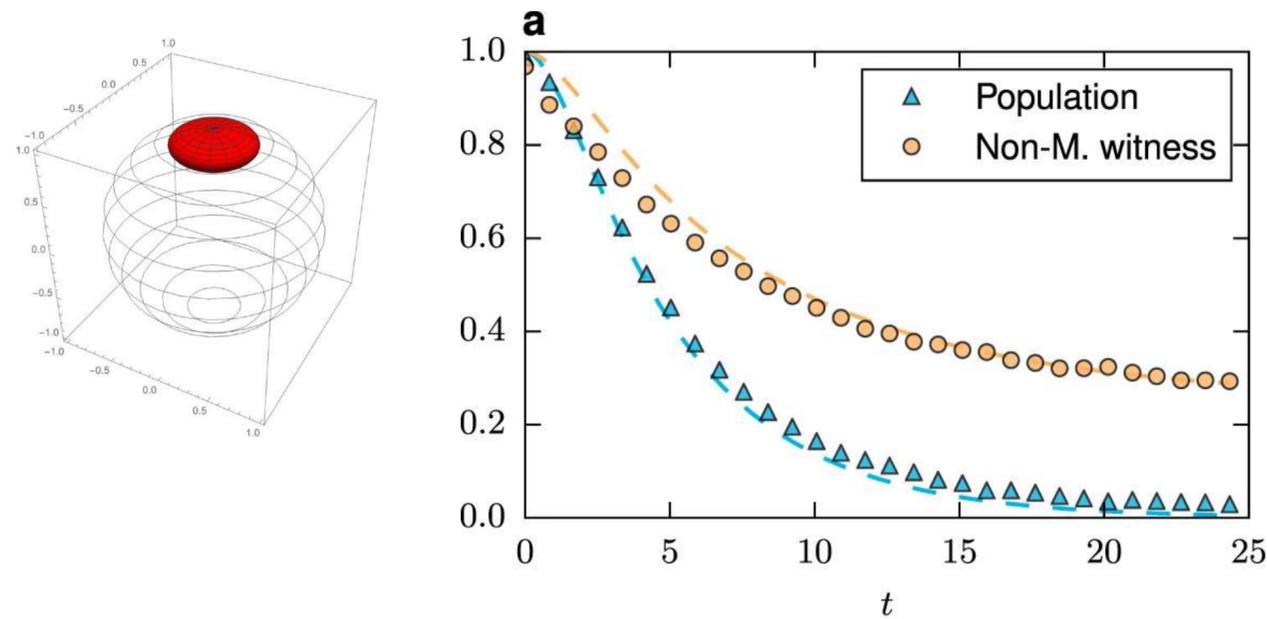

- Access to higher energy levels  $|0\rangle, |1\rangle, |2\rangle, \dots$
- Studying qubit-cavity interaction with JC Hamiltonians
- Characterizing qubit noise, frequency etc.
- Might be very interesting for projects in open quantum systems, metrology, parameter estimation...
- Tutorials on the qiskit textbook

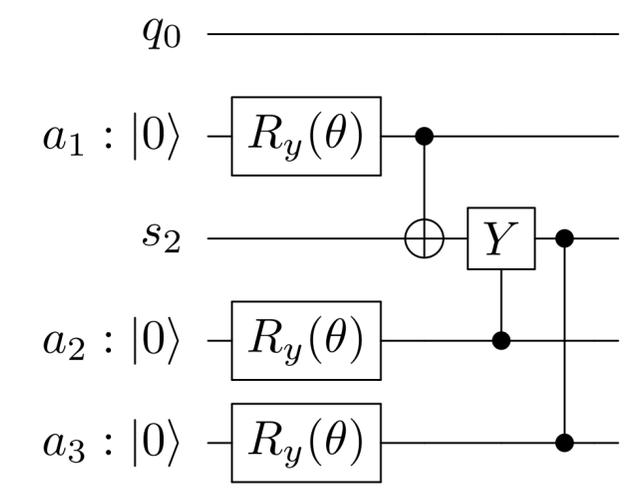

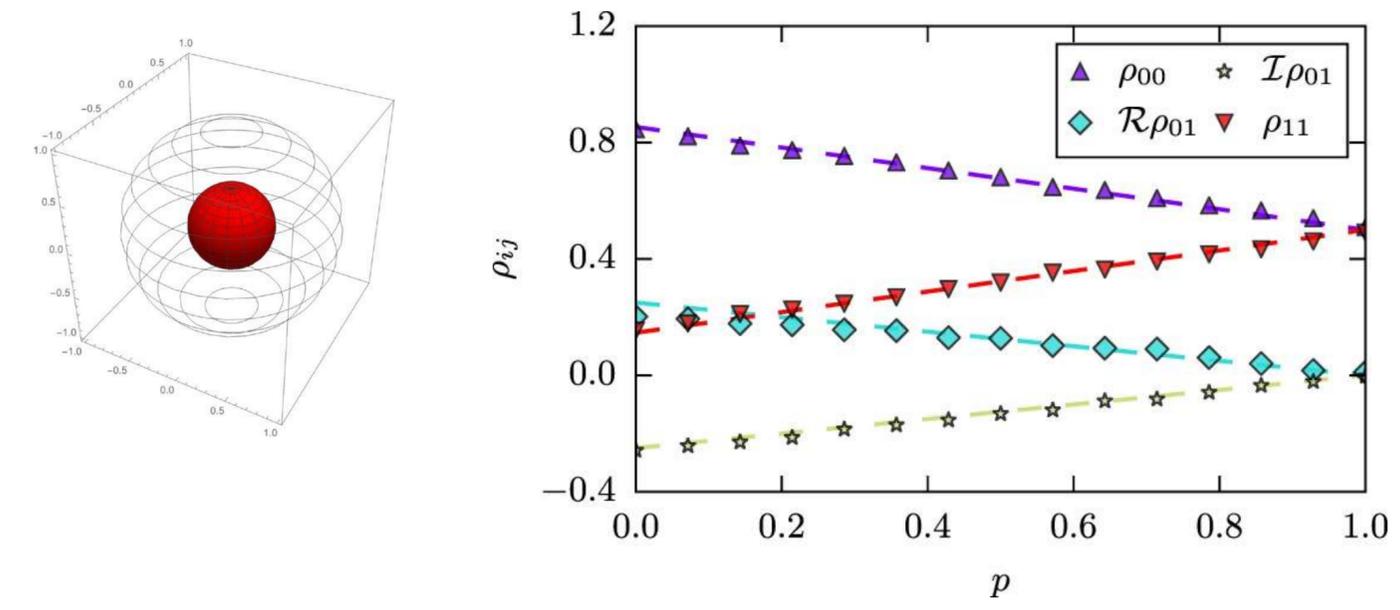

# Example applications

# Simulating open quantum systems

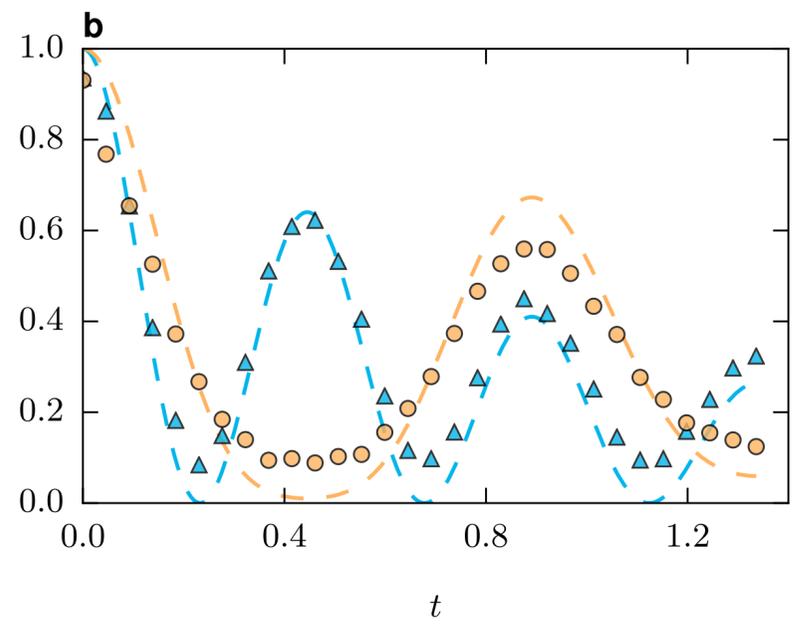

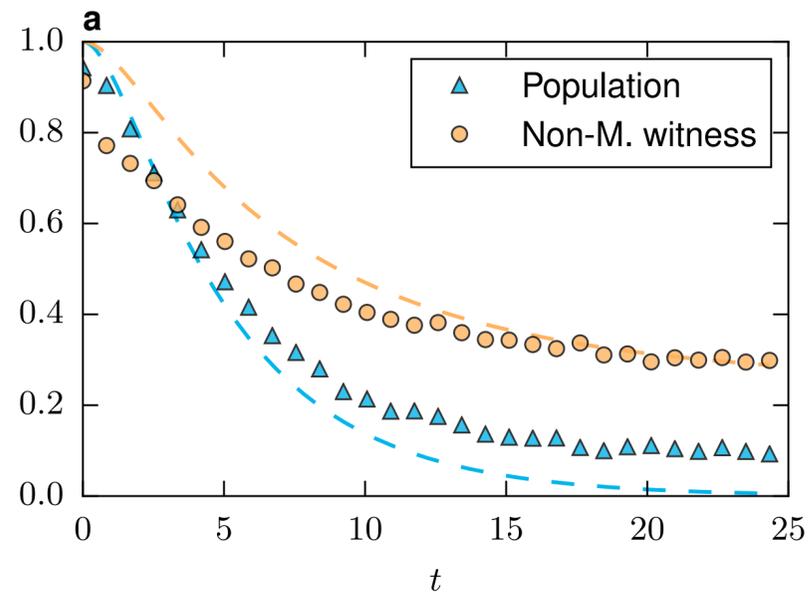

Amplitude damping

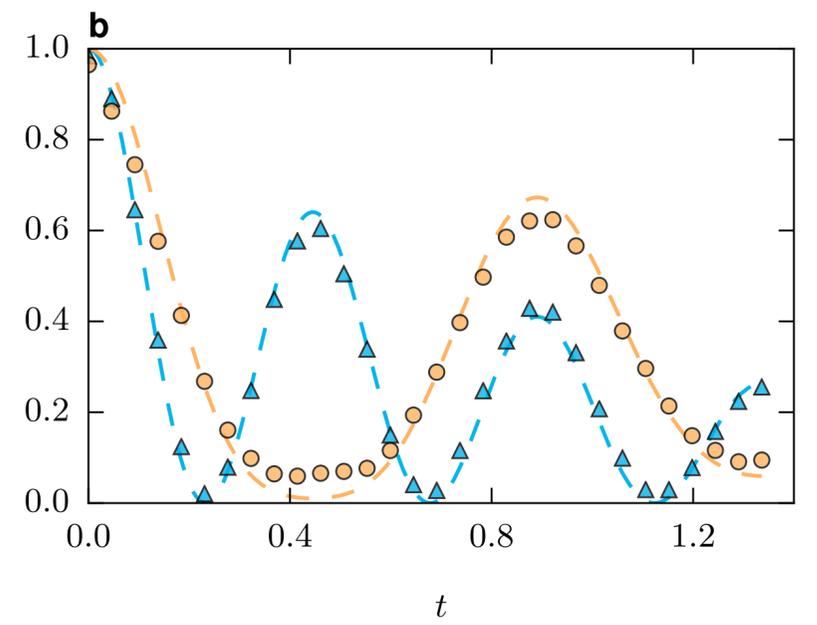

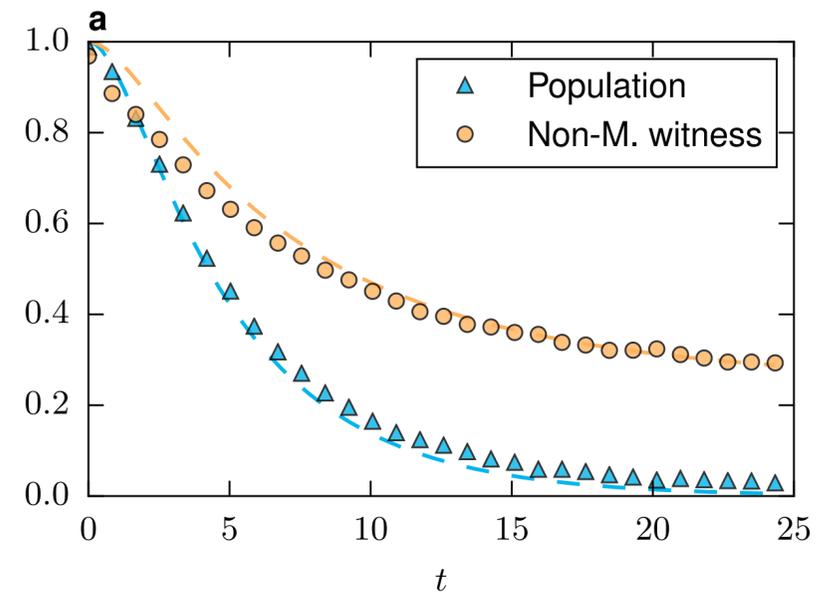

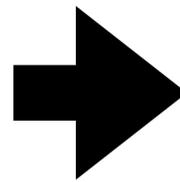

Depolarizing channel

# Simulating open quantum systems

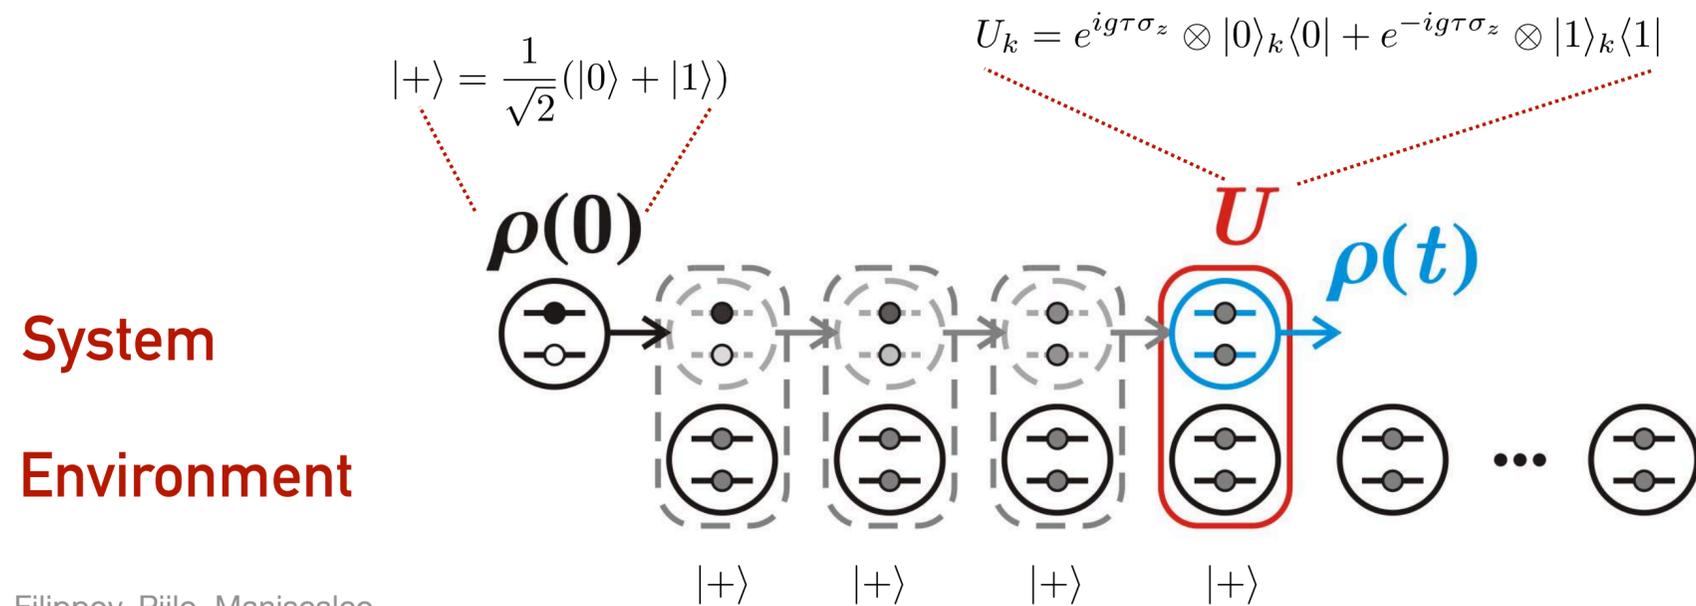

1st submission

# Collisional models

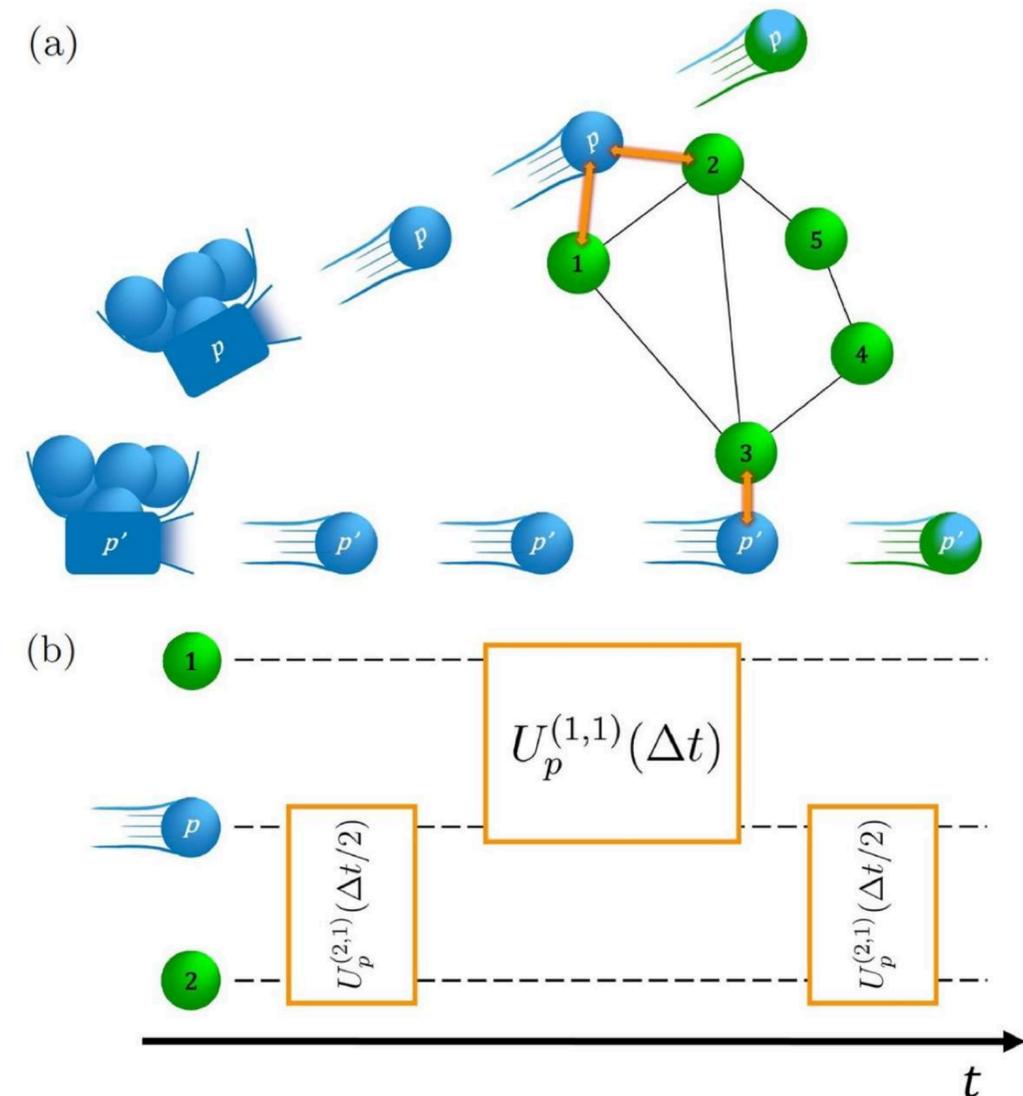

Filippov, Piilo, Maniscalco, Ziman, PRA 96, 032111 (2017)

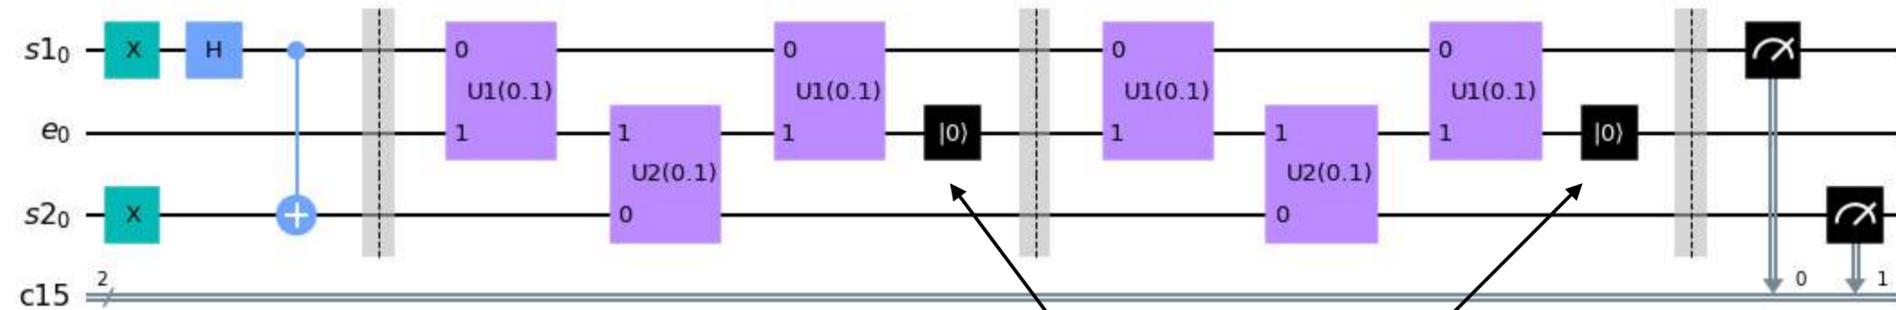

García-Pérez, Rossi, Maniscalco npj Quantum Information 6, 1 (2020)

# Collisional model

- IBM introduced conditional qubit resets in Nov 2020.
- An X gate is applied if the qubit is measured in  $|1\rangle$
- We can reset the state of neighbouring ancillas: no need to swap them with fresh ones!
- We are trying to use this for multipartite collisional models

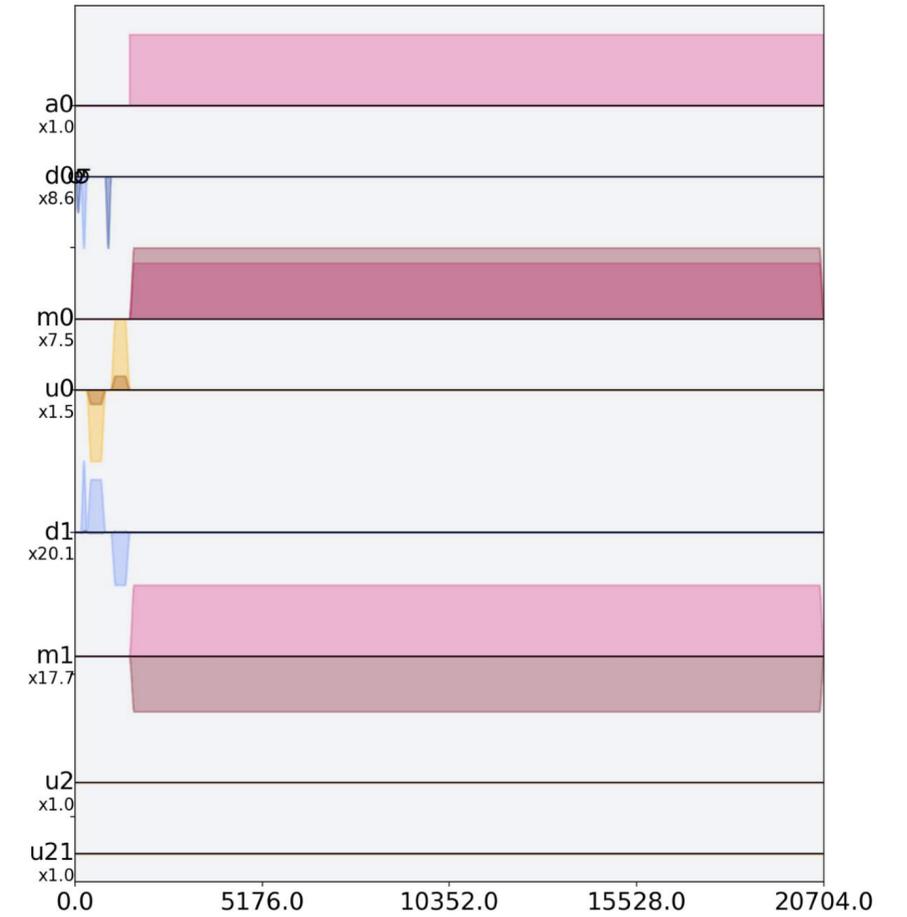

# Collisional models

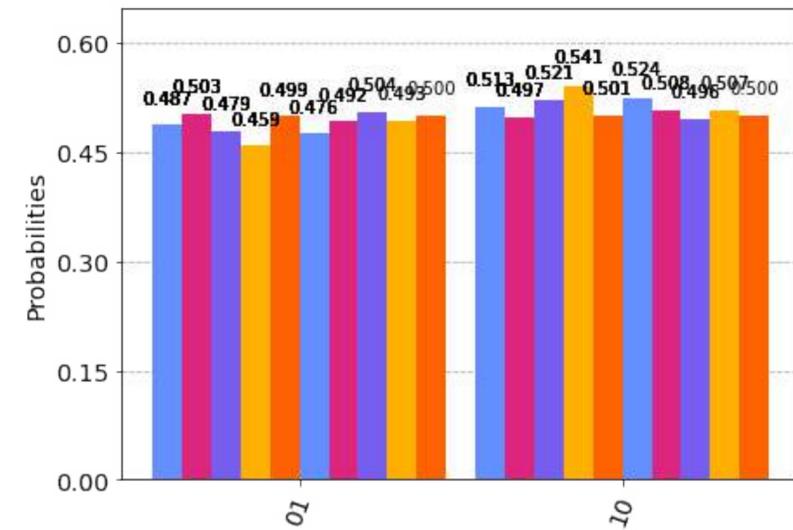

$$|\psi_{-}\rangle = \frac{|01\rangle - |10\rangle}{\sqrt{2}}$$

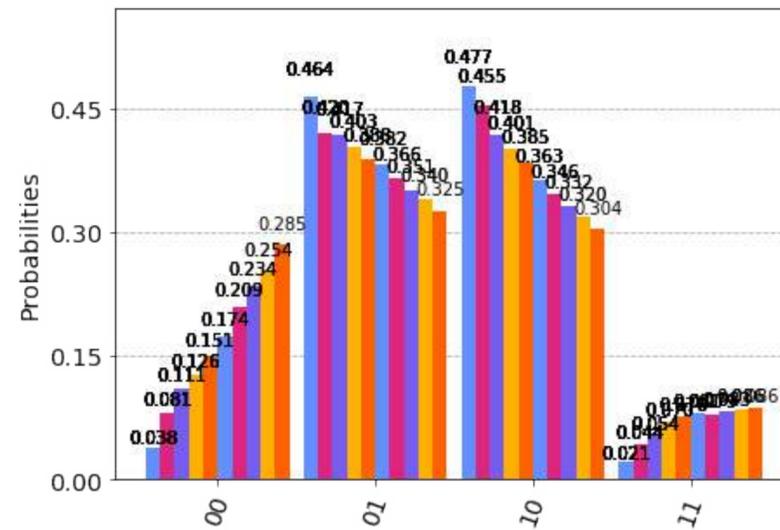

Reset

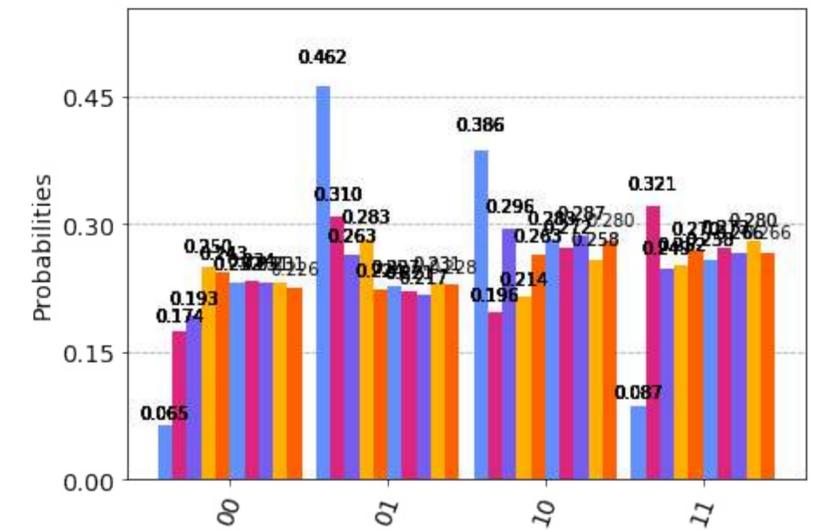

Noiseless simulation

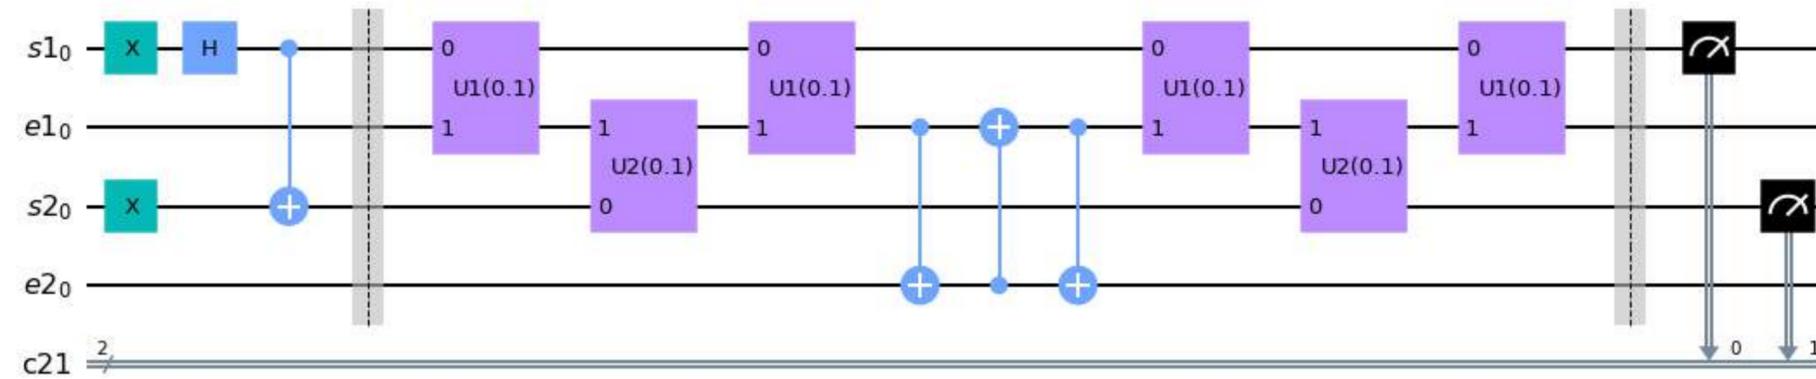

Noisy simulation

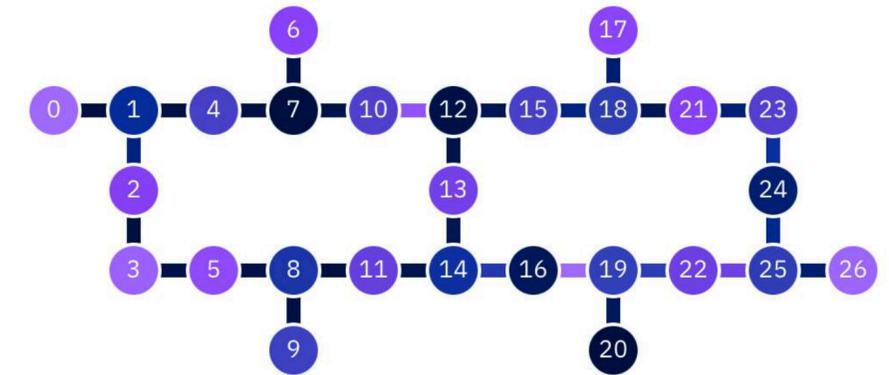

ibmq\_bogota

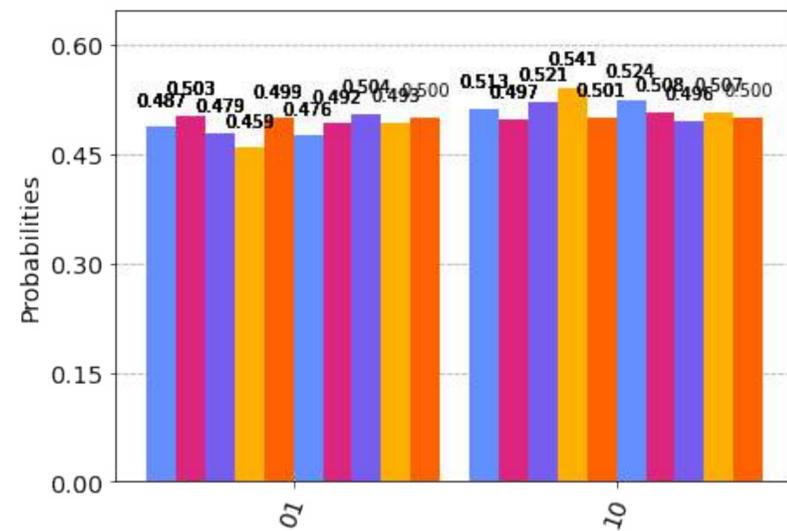

# Collisional models

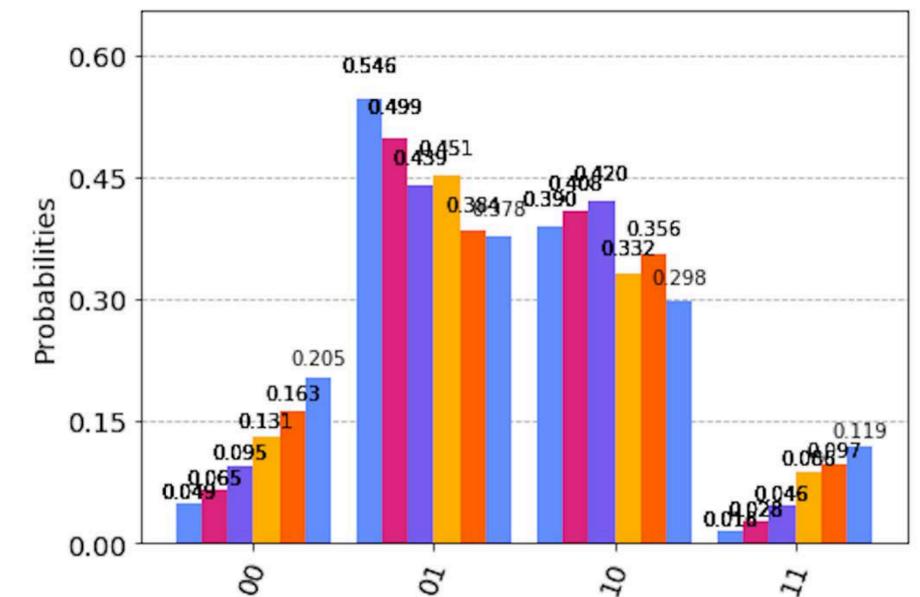

$$|\psi_{-}\rangle = \frac{|01\rangle - |10\rangle}{\sqrt{2}}$$

Noiseless simulation

ibmq\_toronto

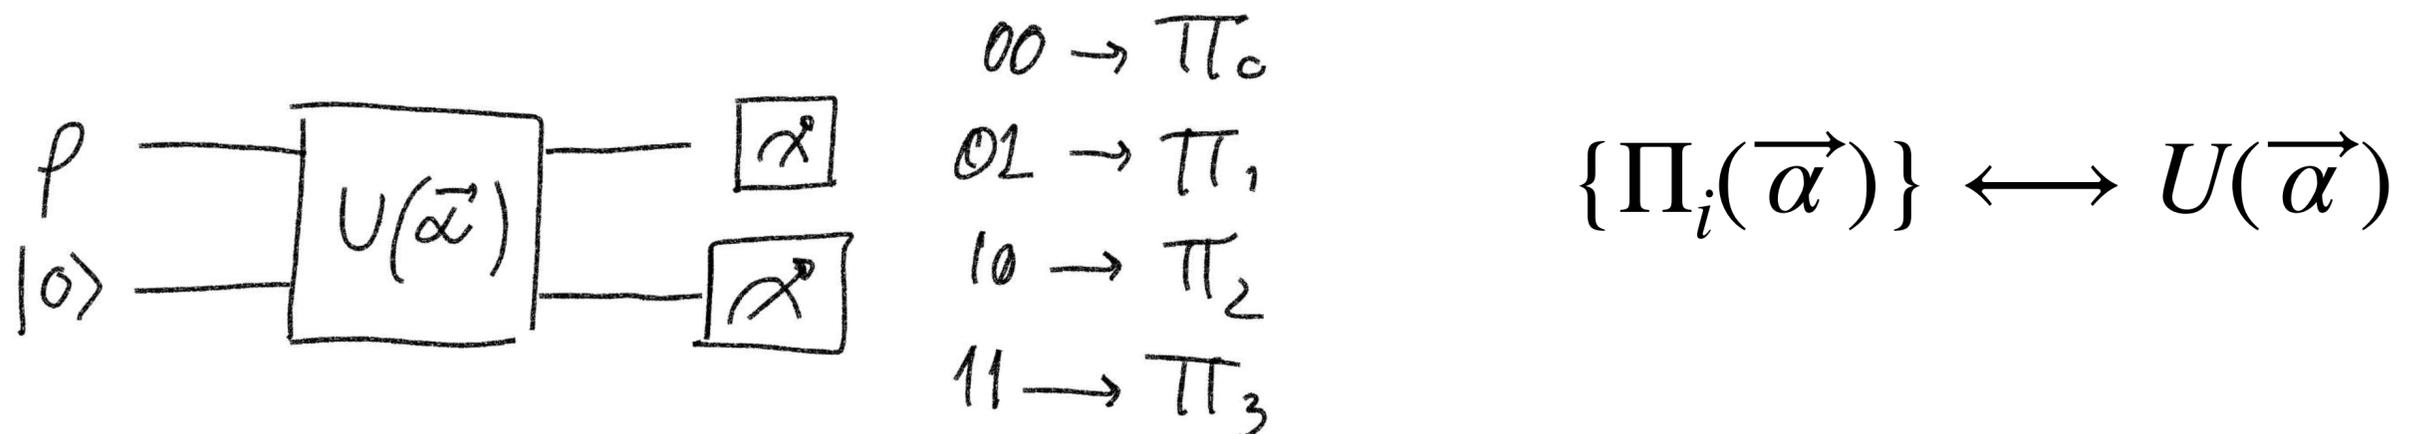

# POVMs

- Generalized measurement with positive-valued operators

$$\{\Pi_0, \Pi_1, \Pi_2, \Pi_3\} \quad \sum_i \Pi_i = \mathbb{I}$$

If they span  $\mathcal{L}(\mathcal{H})$  it is informationally complete ( $d^2$  operators)

- Can be implemented using dilation

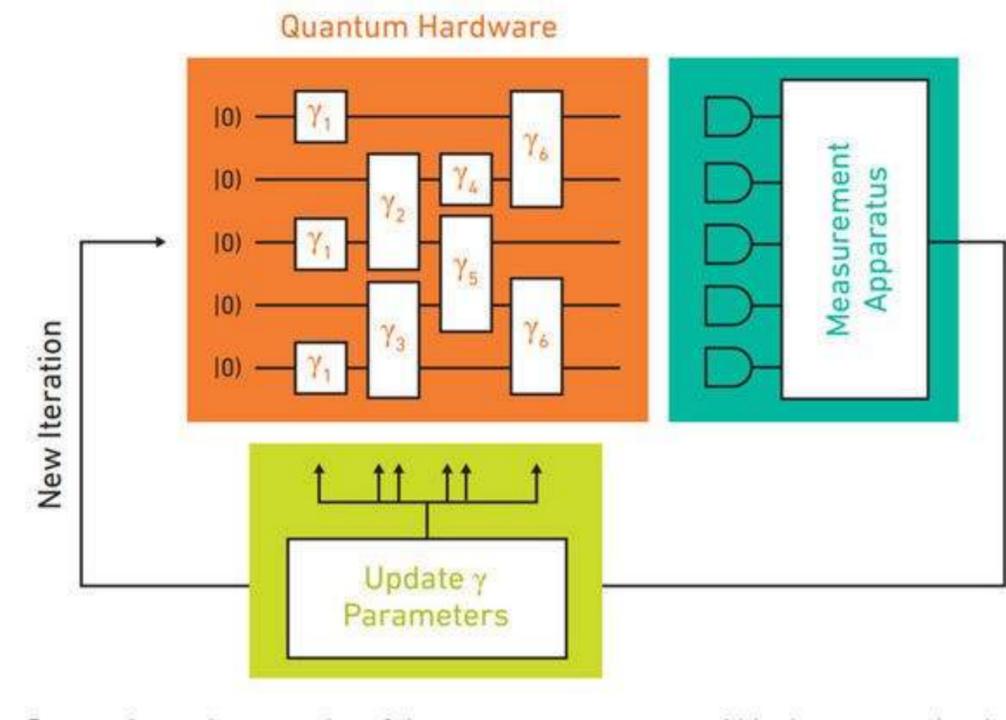

# POVMs and VQE

- Variational Quantum Eigensolver: find an approximate ground state energy

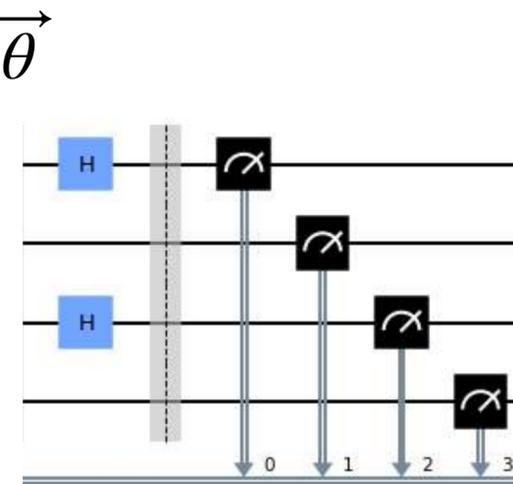

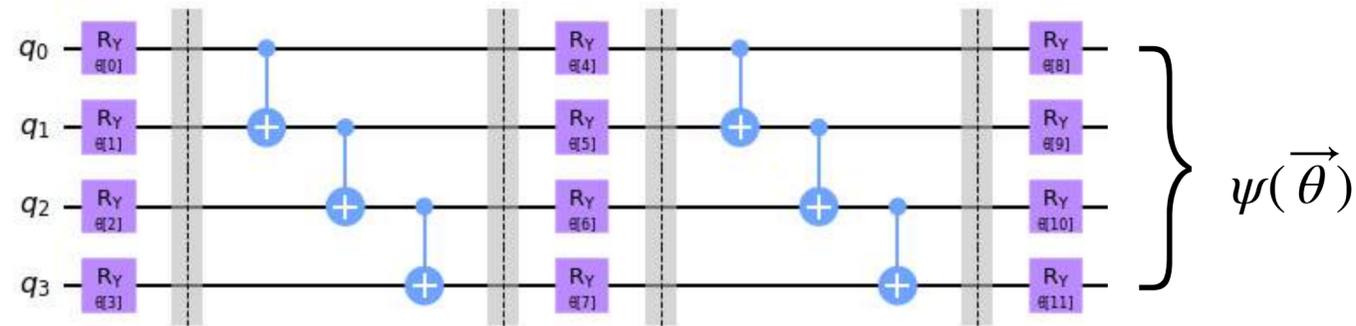

$$\lambda_{min} \leq \lambda_{\theta} \equiv \langle \psi(\theta) | H | \psi(\theta) \rangle$$

- Hybrid quantum-classical algorithm:
  - Quantum computer: state preparation and measurement
  - Classical computer: parameter optimization

# POVMs and VQE

We choose an ansatz state that depends on parameters  $\vec{\theta}$

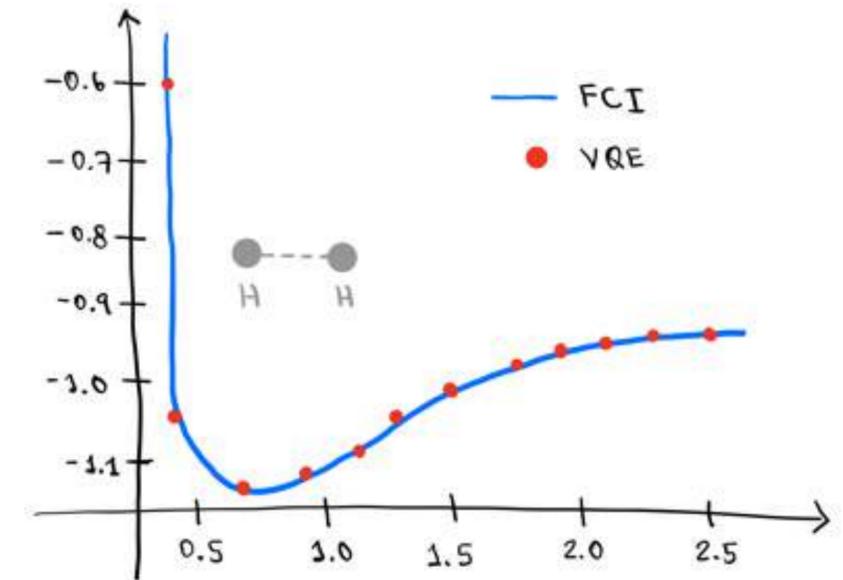

$$P_1 = \sigma_x \otimes \sigma_z \otimes \sigma_x \otimes \sigma_z$$

We evaluate the expectation value of the energy

$$\langle H \rangle_{\psi(\theta)} = \sum_k c_k \langle P_k \rangle_{\psi(\theta)}$$

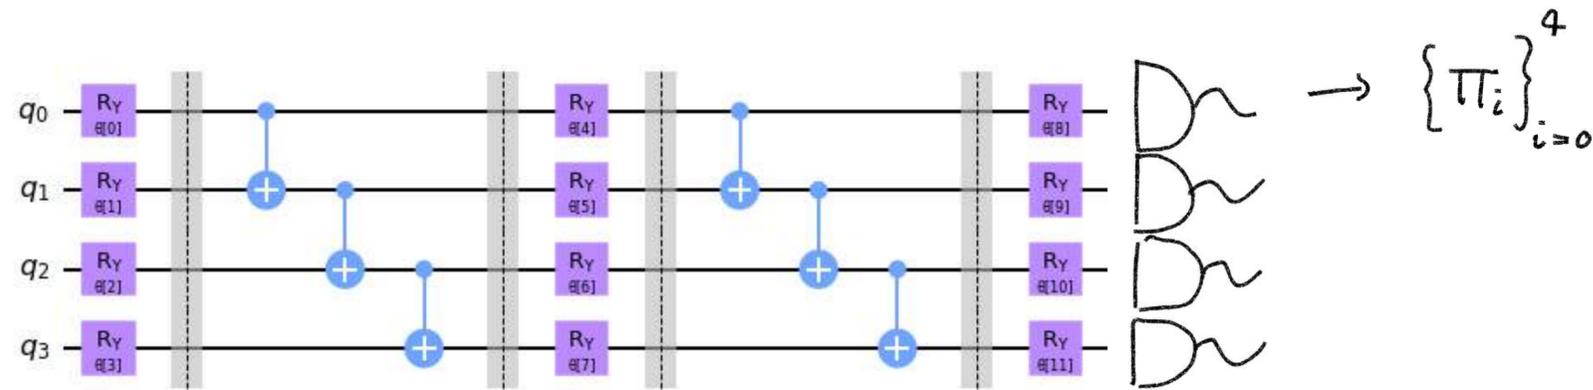

**Measurement problem:** the number of Pauli strings to be measured grows very badly with the size of the Hamiltonian, and hence the number of shots required to reach chemical accuracy

**Solutions:** grouping of Pauli strings that can be measured at once (with marginalization), machine learning, etc...

# POVMs and VQE

Our proposal: perform local IC-POVM on each qubit

$$\langle H \rangle_{\psi(\theta)} = \sum_k \langle P_k \rangle_{\psi(\theta)} = \sum_{\vec{m}} w_{\vec{m}} P_{\vec{m}}$$

$\vec{m}$  is a sequence of outcomes  
 $w_{\vec{m}}$  is the corresponding weight in H (can be calculated efficiently)

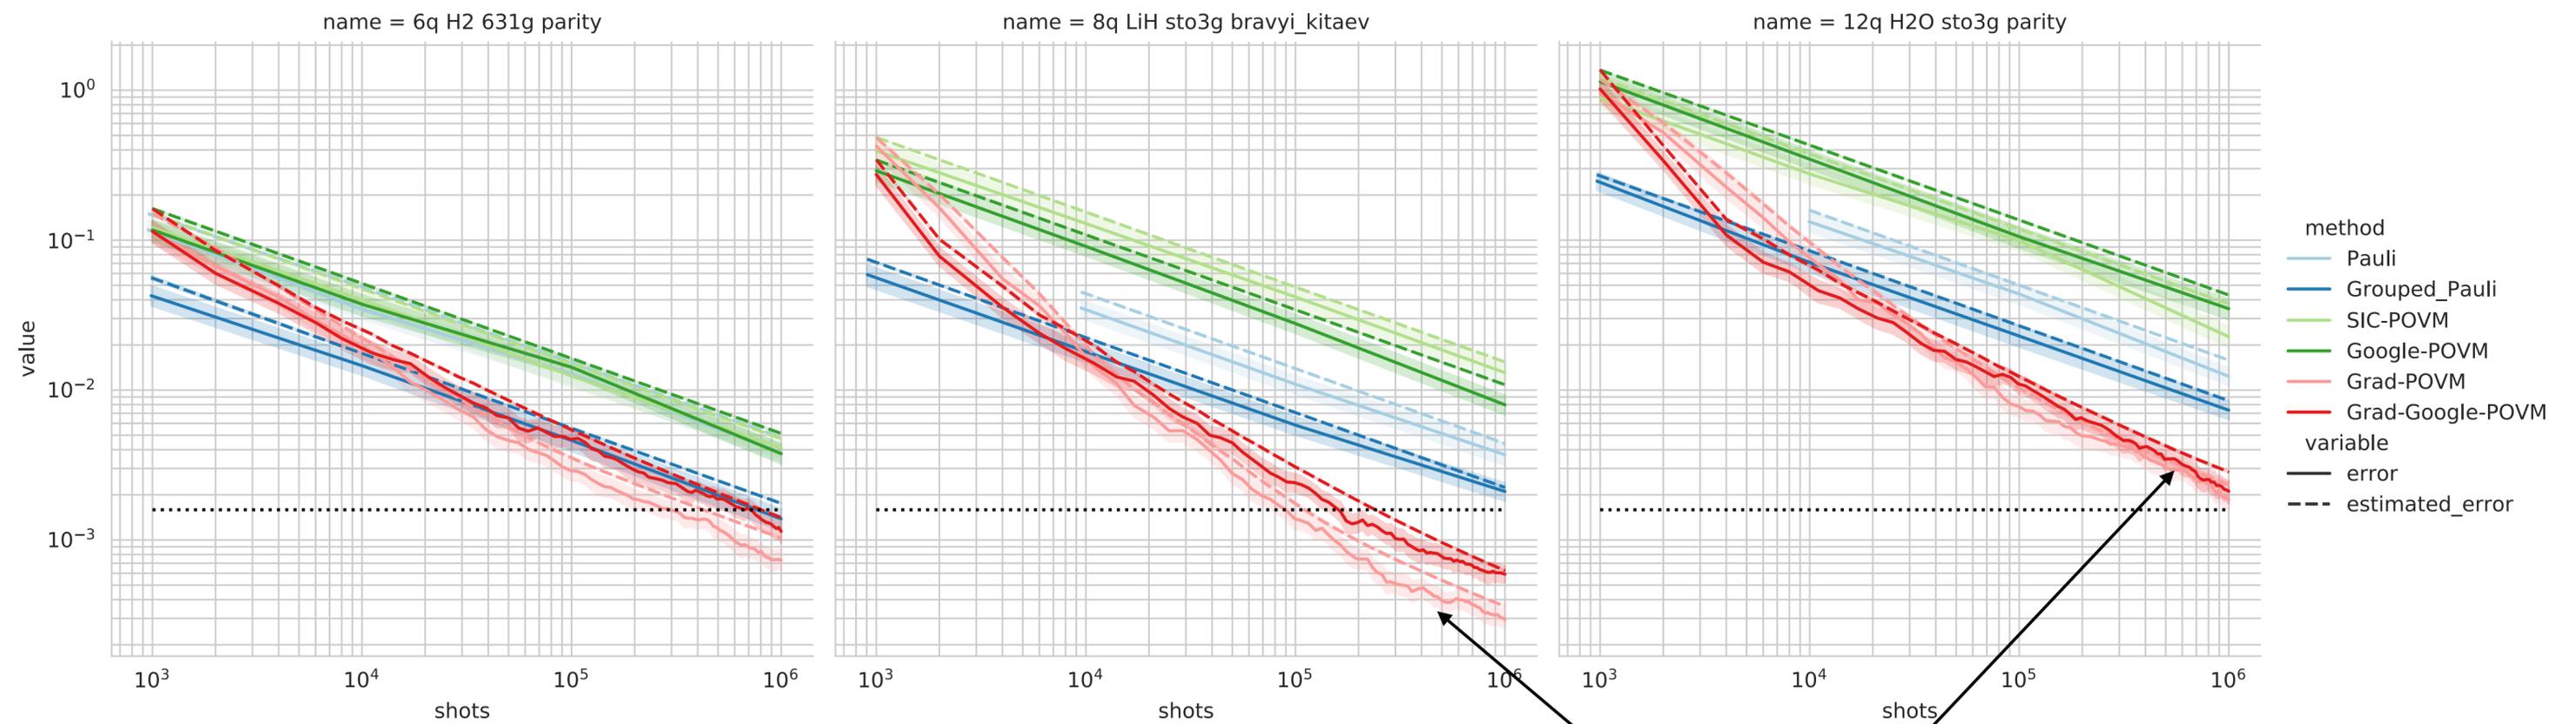

The expectation value of the energy is simply a Montecarlo sampling

Moreover, we have informationally complete data (useful for e.g. partial tomography, quantum subspace expansion etc.)

The POVM operators can be optimized to increase the precision!

# POVMs and VQE

## Results

Gradient-optimized IC-POVM beats state of the art Pauli grouping

# Recap

- Introduction to the limitations of superconducting quantum devices
- How to get the best results from IBM Q devices
- Two research examples in OQS and measurements
- The devices improve fast. Things that may not work now may work in a few months
- New possibilities offered by the pulse level control

**Thank you!**
