Project draft

1. Field of interest

Indicare il settore scientifico disciplinare: AGR-08

2. Project title

Innovative irrigation solutions to improve the sustainability of rice-based agro-ecosystems

3. Tutor (membro del Collegio dei Docenti): *Prof.ssa Arianna Facchi*

- **Eventually: co-tutor/s:** -

4. Relevance of the topic and state of the art:

Rice is the world's most important food crop, because it is a staple food for more than half of the world's population and the world demand for rice will increase by approximately 24% over the next 20 years [Nguyen and Ferrero, 2012]. Rice is cultivated over about 1,300,000 ha in Mediterranean countries [FAOSTAT, 2016]. Although in the Mediterranean region it is currently concentrated in specific areas, rice production has a great socio-economic and environmental importance due to the fact that it is an important staple food for some countries, for the high quality of rice produced, and for its role in the maintenance of biodiversity (many important rice areas are in river deltas, estuaries or coastal wetlands or, however, part of protected ecosystems such as the EU Natura-2000 network). The most important rice-producing EU countries are Italy and Spain in Europe (72% of the EU production; 345,000 ha).

Traditionally, rice is grown in paddies flooded from before sowing to before harvest, thus it requires much more irrigation water than non-ponded crops [Cesari et al., 2016; Cesari et al., 2017; Facchi et al., 2018]. Under flooded conditions, significant amounts of nutrients may be lost by leaching and runoff during the cropping season, with important implications on water quality [Katoh et al., 2004]. Like other important cereals, rice requires a great amount of chemicals, represented especially by fertilizers and pesticides, which can lead to water pollution in a peculiar environment like paddy. Water management has been recognized as one of the most important factors that affect greenhouse gas emissions from paddy fields; in particular, rice paddies are considered one of the most important sources of atmospheric methane (CH₄), producing about 5-20% of the total emission from anthropogenic sources [USEPA, 2006] and approximately 30% of the global agriculture CH₄ emissions.

Mediterranean rice agro-ecosystems are nowadays facing numerous problems, such as the need to integrate irrigation requirements with water resource availability, the protection of the environment, the need to ensure an adequate income for rice producers, the impossibility

of being introduced in agricultural areas characterized by a limited water availability despite the fact that rice consumption in the Mediterranean basin is presently increasing, the lack of specific studies conducted in Mediterranean countries taking into account environmental and socio-economic peculiarities of these areas. Due to these factors, the introduction of water management practices alternative to continuous flooding is highly required to enhance water use efficiency and safeguard environmental quality in Mediterranean rice agro-ecosystems. However, these practices must be tested and adapted to country-specific conditions.

5. Layout of the project (draft)

5.1. Materials & Methods:

The project MEDWATERICE ('Towards a sustainable water use in Mediterranean rice-based agro-ecosystems') was selected and funded under the PRIMA Program-Section2-2018. The MEDWATERICE Consortium consists of 11 Partners from 6 Mediterranean Countries (IT, ES, PT, EG, TR, IL) and includes universities, research centers and private companies. MEDWATERICE aims at exploring sustainability of innovative irrigation options, in order to reduce rice water consumption and environmental impacts, and to extend rice cultivation outside of traditional paddy areas to meet the escalating demand. Case studies will be conducted in pilot farms of the countries involved in the project. Alternative irrigation methods to be tested will be tailored to local conditions using a participatory action research approach through the establishment of Stake-Holder Panels (SHPs) in each country, which will include regional authorities, water managers, farmer associations and consultants, and private companies involved in the rice production chain. For each irrigation approach, innovative technologies and the most appropriate rice varieties and agronomic practices will be adopted to minimize impacts on yield quantity and quality. Data collected at the farm level will be extrapolated to the irrigation district level to support water management decisions and policies. Indicators for quantitative assessment of environmental, economic and social sustainability of the irrigation options will be defined. The participation of SHPs in the project is expected to improve the transfer of project's results to the agricultural sector and decision makers.

Prof. Facchi is the Coordinator of the MEDWATERICE project, which will start on 1st April 2019 and will last for 3 years. The research activity of the PhD student will be developed within the context of this international project.

5.2. Schedule and major steps (3 years):

The PhD program will be articulated in the following main tasks:

1. Collect and harmonize existing data regarding irrigation consumption and environmental impacts of rice cultivation in the main rice producing countries of the Mediterranean area (Year 1)
2. Identify major problems affecting rice production in Italy, and select the most appropriate irrigation solutions (technologies and practices) to be experimented; this task will be conducted through the involvement of a Stake-Holder Panel including the National Rice Research Center, regional authorities, irrigation water managers, rice farmer association and consultants, rice millers and other private companies involved in the rice chain (Year 1)
3. Evaluate the impacts of the selected irrigation options, through field experiments eventually supported by agro-hydrological models. Environmental sustainability (including

water efficiency) and on the on-farm economic balance for the different irrigation options will be quantified (Years 1, 2)

4. Upscale the on-farm water use efficiency and environmental impact of alternative irrigation management options to the irrigation district level, by using an appropriate agro-hydrological model (Years 2 and 3)

5 Define and apply an appropriate techno-economic, social and environmental impact indicator set, to evaluate the overall sustainability of the different rice irrigation options, identify the barriers to their adoption and propose actions to overcome the obstacles; this will be achieved by involving the Stake-Holder Panel identified at the beginning of the PhD project (Year 3)

6. Available funds (source and amount)

RISTEC “Nuove tecniche colturali per il futuro della risicoltura” (Regione Lombardia, PSR Operazione 1.2.01, ottobre 2017 – marzo 2019), amount for DiSAA: 210,000.00 euro.

MEDWATERICE “Towards a sustainable water use in Mediterranean rice-based agro-ecosystems” (PRIMA Program-Section2-2018, aprile 2019 – marzo 2022), amount for DiSAA: 200,000.00 euro.
